And is not Dr Todd a little hard on Service medicine? After all, what could be vaguer than "unfit to fulfil Army physical requirements," a designation under which many are discharged Moreover, his suggested phrase "short fever of undetermined origin" bears a striking resemblance to the "P U O" so familiar thirty-five or more years ago

Definitions, labels, the conception of disease as distinct from disparate disease types—these and kindred matters were dealt with in a Skinner lecture by Sir Henry Cohen [1] with rare and characteristic clarity

> "The first stage in the diagnosis of disease is the recognition of simple quantitative deviations from the normal"
>
> "A complete diagnosis must tell us where disease is, what functional disturbances are present and how these have arisen, and only in so far as diagnosis answers all these questions is it complete"
>
> "There are no diseases, only disease"
>
> "Yet a further function fulfilled by diagnosis, and herein lies the importance of accurate labelling, is that it shall serve as a means of *conceptual shorthand* by which experience can be pooled"

Finally Dr Todd urges that doctors should view their diagnostic problems with humility, and realise how often they are in the dark If anything *can* teach that lesson, it is the practice of medicine

Liverpool S BARTON HALL

SIR,—Rarely is an opportunity missed of echoing Trousseau's "il n'y a pas de maladies, il n'y a que des malades" Dr Henderson (Jan 3) is among many who deride the notion of the "reality" or the "existence" of disease entities "disease names do not represent real *things*" he writes

It is not altogether clear what they mean by "entity," "thing," "real," or "exist" They seem either to assert that diseases are not physical objects, which is a true but not very important observation, or to imply that "entity," "reality," or "existence" can be predicated only of physical objects, which is false Any process, including those we call diseases, that can be seen to be a unity, having a characteristic evolving pattern, can be called a "real entity"

There are both patients and diseases Both exist Precision in diagnosis demands a knowledge of the natural history of diseases, and to think that, like the unicorn, they have no existence is singularly unhelpful

London, W 1 KENNETH STONE

TREATMENT OF BULBAR PARALYSIS

SIR,—With reference to Professor Lassen's interesting article (Jan 3) concerning methods of overcoming the problems created by bulbar paralysis in poliomyelitis, I wish to draw attention to the use of a rectal drip, which I have found very helpful in this condition These patients are not well able to tolerate tubes in the mouth, throat, œsophagus, or stomach Such intubation causes increased salivation and occasionally vomiting, apart from the discomfort, and it increases the risk of aspiration pneumonia On the other hand, fluid is well retained in the rectum, retention being aided by the weakness of the bowel and abdominal wall and the postural drainage position

Waddon Hospital
Croydon. J J LINEHAN

THE ANKLE BLOW-OUT SYNDROME

SIR,—May I congratulate Mr F B Cockett and Elgan Jones on their paper in your issue of Jan 3 consider that this work is as significant in connexion with ulceration about the ankle as was that of Brod 1846 and Trendelenburg in 1891 in connection with treatment of varicose veins They have added preci to what we knew only generally

These incompetent "blow out" ankle veins can felt on firm thumb pressure behind the posterior bord of the tibia 3–6 in above the tip of the internal malleol and more certainly when the patient is lying down the leg is held up vertically The orifices of emergence feel like buttonholes in the deep fascia

Dr Ferdinand Martorell, of Barcelona, has alrea described these important vessels in his book on Var and also the method of block excision of the ulcer a pigmented skin with the superficial and deep fascia ligation of the faulty communicating veins in the He immediately sutures a Padgett skin graft to t defect, and he reports good results, although he admitted to me in September, 1952, that they sometimes bre down In my practice of ligation only, the wound edges have often necrosed after ligation of these inefficient communicating veins, forming yet another ulcer which takes some time to heal this adds support to the block excision and skin graft I regard this procedure ligature of a communicating vein above the ankle as a major one and think that it should be undertaken only by those trained in this work

London, W 1 HAROLD DODD

WATERHOUSE-FRIDERICHSEN SYNDROME TREATED WITH CORTISONE

SIR,—With reference to the article by Dr Breen and his colleagues [1] I think that a case treated by me la October should be put on record

A man, 47 years of age, awoke one morning with general malaise, severe headache, and severe aching pains in all four limbs I saw him at 9 A M and found a temperature of 103°F with moderate tachycardia and no other signs Influenza was provisionally diagnosed, and he was given sulphadiazine 1 g four hourly together with routine symptomatic treatment That evening his temperature was 101°F, but his headache and limb pains continued and he had a bad night

The next morning his symptoms were unchanged, but he had developed a widespread purpuric rash There was no neck rigidity, Kernig's sign was negative His temperature was 97°F and his blood pressure 80/55 mm Hg, normally his B P ranged from 120/80 to 150/95 Arrangements were made for his admission to hospital as a case of Waterhouse Friderichsen syndrome By 2 P M he was given aureomycin as well, and he was given 100 mg of cortisone parenterally

At 5 P M he was seen by Dr J Markell in consultation There were still no clinical signs of meningitis, although a lumbar puncture revealed a turbid cerebrospinal fluid at a pressure of 160 cm of water The cell count was 1170 per c mm, nearly all polymorphs, *Neisseria meningitidis* was present, but culture was sterile At lumbar puncture the opportunity was taken to inject 20,000 units of penicillin in saline intrathecally

At 7 P M the patient became confused and attempted to get out of bed Shortly afterwards he had a fit and entered status epilepticus He never regained consciousness and died in coma at 9 P M

Although the prognosis for a man of 47 with Waterhouse-Friderichsen syndrome is always grave, we were shocked at the sudden deterioration that occurred at 7 P M We came to the conclusion that this rapid deterioration might have been due to the cortisone, especially in view of its known inhibitory effect on fibrosis and healing

After reading the account by Dr Breen and his colleagues, and noting the convulsive episodes in both ich as phosphorus and petrol; and the full thickness of he skin was not invariably destroyed.

TREATMENT

The efficiency of the evacuation plan and the surgical arrangments has undoubtedly meant that a greater proportion of seriously wounded men have been saved than was the case in the major battles of 1939–45. Our own units have continued to use plasma as the chief means of replacing colloids and electrolytes in initial treatment; serum jaundice was occasionally troublesome in the early months. Plasma is available to our forward units from British or Canadian sources; and when fresh blood is needed it is obtained from donors on the spot or from Commonwealth headquarters in Japan. The Americans have depended more on fresh blood, which has been flown from the U.S.A. in large quantities. Dextran is being used by both Commonwealth and American medical units.

For wounds of the limbs and trunk delayed primary suture has been used in Japan, after a thorough primary excision and toilet at the M.A.S.H. five days earlier. Penicillin in full doses has been given as a routine from the day of wounding; and very few penicillin-sensitive organisms have been found in the wounds on arrival in Japan. A proportion of the burns have been treated at Kure by the open-exposure method, which has given good results; but exposure is not a practicable method during evacuation. Men with deep burns have stayed at Kure until the primary resurfacing of the burned area has been completed. Treatment has been based on surgical excision of sloughs, and, in extensive damage, on multiple early free-grafting, chiefly with patch grafts. The massive wounds have also been promptly covered by free-grafting both at the M.A.S.H. and in Japan.

RESULTS

The results seen when the casualties return to this country leave no doubt that a very high level indeed of primary reparative surgery has been maintained—particularly by delayed primary suture. Burns with full-thickness skin-loss have arrived in England healed, with a complete primary skin surface, six to eight weeks after injury. Massive wounds of the limbs and trunk, often with multiple fractures, have healed quickly with early skin cover. Although exact figures are not available, quite exceptional results seem to have been obtained after wounds penetrating the abdomen and the dura; here helicopter evacuation has been of the greatest importance. The high quality of the units fighting for the United Nations in Korea is clearly matched by the standard of the medical services helping to support them.

METHODS OF TEACHING

THE traditional techniques of medical teaching, in the lecture-theatre, at the bedside, or in the outpatient department, have drawn some fire in the past few years. The importance has often been urged of teaching the teacher to examine his methods critically and to adapt them to the particular needs of his subject and his students. Moreover, it has been argued that the student should fend more actively for himself by taking a dynamic part in his own education. Means to these ends were among the matters discussed at a conference on the Technique of Medical Teaching held at the Postgraduate Medical School of London on Jan. 9 and 10. The conference, which was the third of its kind sponsored by the medical school,[1] included for the first time a number of short demonstrations of teaching methods, given by members of the staff to students borrowed for the afternoon from St. Mary's Hospital.

TEACHING AND LEARNING

At one of the sessions, Prof. G. PAYLING WRIGHT discussed the balance between teaching and learning. He thought that the emphasis in our medical schools was on teachers teaching, rather than on students learning. The medical student could with advantage be called on for more emotional and intellectual activity during his own education; for the object of his training was to turn out a doctor who could stand alone, independent of his teachers, and who could continue to learn by his own efforts. To keep abreast of medical progress, most doctors had to rely very largely on their reading; and students should be introduced to library work and methods, with which few of them gained any close acquaintance at present. How many students knew, for example, how to use the *Cumulative Index Medicus* or the *Index Catalogue* of the Surgeon-General? If the student spent more time in the medical school library, not in systematically reading the standard textbooks but in following up the conditions he saw in his patients from day to day, he would fortify the intellectual stimulus by the emotional one which sprang from his contact with the patient and his problems.

Professor Payling Wright said that the plan of trying to teach general principles in the early stages of the clinical course might have to be modified. He thought that lectures for junior students should provide them with a good deal of factual knowledge, which they must acquire before they could appreciate the general principles. It was not until later in the clinical period that the stimulating and inspirational type of lecture became more suitable. A tutorial system could usefully supplement the lecture course and encourage more active learning: at Harvard, for example, small groups of clinical students met in the evenings to discuss with their tutor, and perhaps with a member of the hospital staff, a paper prepared and presented by one of the students. Another help was a journal club which met fortnightly or so to consider recent articles in the leading medical journals.

Sharing the general concern at the size of the medical curriculum and the stress it placed on the student, Professor Payling Wright suggested that preclinical subjects be taught and examined at two levels, and that the student be given the option of taking, say, either anatomy or physiology at the higher level. Such a provision for specialisation at quite an early stage in his career would relieve the student of some of his burden. Much of the day-to-day teaching of anatomy was given by graduates working for the primary fellowship examination, who tried to raise the student's knowledge to what was, in Professor Payling Wright's view, an unreasonably high level for all to attain.

As a means of improving and maintaining the standard of clinical teaching, Professor Payling Wright commended the staff round which was a regular feature in many American teaching centres. This round, which was generally restricted to senior members of the staff, stimulated enlivening debate among the teachers and so brought out new ideas which were presently reflected in the teaching to students.

Prof. J. MCMICHAEL agreed that the staff conference was the best way of keeping teachers up to date and in tune with one another; and Prof. IAN AIRD, recalling some lively meetings he had attended in the United States, pointed out that the staff round in this country lacked the historical prestige that it enjoyed there, and that in consequence busy consultants were not always ready to set aside two or three hours each week for this purpose.

TEACHING DEMONSTRATIONS

The young men who tackled the discour of teaching before teachers did well to de costal movement and no further improvement during the *next 110 min A pint of whole blood was given The patient's* condition remained satisfactory on 100% oxygen with intermittent gently assisted respirations 20 ml of nikethamide had no effect

---

[1] See *Lancet*, 1951, i, 1408.

At this stage feeble finger, toe, and facial twitches were apparent The endotracheal tube was removed, and the patient made ineffective attempts to clear her throat She was obviously recovering consciousness, though still paralysed

Though it normally potentiates the effect, there seem to be some theoretical grounds for giving neostigmine in these cases,[11] and here it was given slowly in dilute solution After a total of 2 0 mg over 3–4 min there was a dramatic response The patient was able to move freely and to talk coherently, and she was safely returned to the ward 5 min later, fully conscious Remarkably, next day she had no recollection of the experience

It is most unlikely that the early small dose of tubocurarine, after which adequate intercostal respirations continued for 40 min, *had any effect on the paralysis that followed 90 min* later and persisted for a further 2 hours The thiopentone and pethidine were also given early and, had either been the cause, 20 ml of nikethamide should have produced some response, for it has been shown to be a most efficient antidote to overdoses of pethidine[12]

Blood taken the day after the operation provided further evidence in favour of a succinylcholine paralysis The Hb was 64% and the serum cholinesterase level was 50 units (normal for this method 130–310 units) A fortnight later it was 45 units, and the Hb was 61%

In this case there was an extremely low plasma-cholinesterase level This is the main factor in all true prolongation of paralysis[13 14] It is not certain, however, whether all the reported cases have had true succinylcholine paralysis, for with the exception of Dr Bourne's cases,[4] information about the serum—not the whole blood—enzyme levels is lacking

Dr Lehmann[14] says that Callaway et al[15] have shown that "there is little chance of encountering such a case" (of low serum pseudo-cholinesterase) "*in an average* sample of the population" As the work quoted is based on the levels found in Servicemen "fit for full combat duty anywhere" and healthy civilian blood-donors, I cannot agree that this is necessarily true of the average "anæsthetic population" Preliminary examination of the figures from the preoperative cases I have collected tends to confirm this opinion Preoperative treatment may indeed mask the effects of chronic malnutrition and anæmia, both of which lower the cholinesterase activity of the blood Regeneration is very slow[16] and cannot easily be corrected in short periods Transfusion of packed red cells does not raise a low plasma-enzyme level, and stored blood has been shown to lose its cholinesterase activity rapidly[17]

Naturally, conditions which cause a low plasma-enzyme level should be avoided Anæmia, liver disease and malnutrition have been mentioned, and I would add patients who have been recently transfused to raise their hæmoglobin to levels otherwise acceptable to the surgeon Dr Barnard also mentions the effect of X radiation

I consider succinylcholine to be a relaxant unparalleled for effect, general flexibility, and lack of side effects, and I have used it successfully in nearly 800 patients, only 2 of whom have given me any anxiety The second patient, though not entirely similar to the first one described here, also took a long time to recover, and had been transfused over a short period from a grossly anæmic state to a superficially safe level In both these cases the choice of the drug was probably unwise and would have better avoided

From Dr Barnard's observations it now seems that anæmic patients may be protected from unexp prolongation of paralysis by the infusion of cholinest concentrate

Rubin et al [1] found liver damage with jaundice and (in one animal) a decrease of the erythroid cells in the bone marrow after administration of large doses (25 mg per kg body-weight) of isoniazid to dogs Benson et al,[2] in their long-term experiments with large doses of isoniazid fed to rats, observed a depression of the average leucocyte count and an increased cellularity of the bone-marrow, with a relative reduction in the number of adult neutrophils

It seems that in man there are big individual variations in the sensitivity to isoniazid, even when it is given in the usual dosage for a short period It is debatable what part the streptomycin and P A S played in this agranulocytosis The clinical signs did not appear until three weeks after streptomycin was stopped, it was also at this time that the rapid fall of the granulocytes was discovered These *two facts, together with the* prompt recovery, suggest that streptomycin was not to blame On the other hand, the concomitant jaundice and the restoration of the granulocytes soon after the withdrawal of isoniazid support the view that isoniazid was the cause At all events, the animal experiments I have mentioned and Dr Ferguson's observation indicate that there is a strong case for careful hæmatological control during isoniazid treatment

GONORRHŒA IN ANCIENT ROME

Sir,—It is true that clear references to venereal disease are scarce in classical literature Considering the undeveloped state of nosology, the taboo surrounding the subject, and the wholesale destruction of most of the writings of that period, this is perhaps not surprising Even our own acquaintance with venereal disease might appear rather fragmentary to our successors if nothing were left of our literature except a few dozen non-medical books, chosen at random, and half a dozen texts on general medicine

Even so, Dr Vertue (Dec 20) probably wrongs Juvenal in stating that he never mentions gonorrhœa "Podice levi cæduntur *humidæ*, medico ridente, *mariscæ*" may be taken to refer to gonorrhœal condylomata which is the form of the disease which seems to have received most attention from the ancients This is not surprising in view of the climatic and hygienic conditions in classical Rome

Dr Vertue certainly misrepresents Celsus, who devoted most of the 18th chapter of his 6th book to infectious afflictions of the genital organs The apologetic preamble to this chapter provides at the same time a clue to the reticence of classical writers on this subject Lanceraux in his treatise on syphilis quotes Martial, and states that he was embarrassed in making his choice because the epigrams of this writer are so fertile in references to the contagiosity of venereal disease He also mentions in addition passages from Hippocrates, Natalis Comes, Aretaeus, Galen, Aetius, Oribasius, Marcellus Empiricus, and Dion Chrysostome

The Roman argument in favour of prostitution—namely, that it preserved the chastity of the home—has been used by protagonists of prostitution through the centuries and up to our own times, and cannot therefore be adduced as evidence *for the absence of gonorrhœa* The natural history of this disease tends to be forgotten in these days of universal and effective treatment, but there can be no doubt that untreated gonorrhœa will proceed to resolution and cure in the majority of cases Casanova, for example, cured himself again and again by a simple regimen comprising little more than rest, diet, and temperance

In my limited reading of the classics, I have not come across a reference to the acute urethral *stage of gonorrhœa* as convincing as that in *Leviticus* xv but this itself should serve to allay some of Dr Vertue's doubts, for, if the disease was rampant on the eastern side of the Medi ranean, it is entirely improbable that the master r should have been spared

Sir FRANCIS CHAMPNEYS AND THE MIDWIVES ACT

Sir,—In the reports of the festivities to celebrate th 50th anniversary of the passing of the first Midwives Act and the birth of the Central Midwives Board, it is surprising to see so little reference to Sir Franci Champneys, who did so much to promote the Bill a was the first chairman of the C M B from 1902 until h death in 1930 However great his part in promoting th Bill—and I understood from some who worked wi him that his was the main driving force behind it— was his administrative ability, patience, firmness, an tact, as chairman of the C M B, which made possible th implementation of the Act and the development of th great profession of midwives as we know it today

Prior to the passing of this Act, midwives as a whole we drawn from a poor social class, often quite illiterate, and th training was of the scantiest, while, in many instances, th handy woman, without any training, was in charge

The Act of 1902 forbade any woman to attend a confinem unless she was on the register of the C M B and laid down period of resident training in a maternity hospital and th passing of an examination for those who aspired to th To tide over the period until a new generation of bett trained women was available, the old midwives had to b employed and the first register consisted of those who h been in practice as midwives for a year before the passing o the Act Some latitude had to be given, and I think m memory is not at fault in placing the date as Jan 1 190 after which date no woman could be placed on the regis unless she had completed the prescribed training and pa ed the C M B examination

In Manchester, and no doubt in other centres, the fi "inspector of midwives" commenced her duties on this d and it happened that I commenced my 3½ years as resid obstetric officer to St Mary's Hospital, Manchester, on th same day In this post I had the usual responsibilities of senior resident for the hundred obstetrical and gynæcolo beds in the hospital and, in addition, complete responsibilit for a large home district in which 3000–4000 confinements p annum were attended by hospital district midwives, eve one of whom was now on the register by virtue of hav been in practice before the passing of the Act Many of th women had acquired much clinical knowledge and the gr majority were devoted to their patients and their work, b with a few notable exceptions, they were drawn from a p social class with little education Some were almost illiter and incapable of absorbing anything from the cours lectures they had attended while few of the others under the meaning of "sepsis" and "antisepsis" and still pref a little freshly rendered lard as a lubricant

These I think were a fair sample of the midwives of th country, and the task of the C M B was to keep the midwif service of the country functioning while by *slow degrees* th replaced the worst offenders by newly trained midwives a educated the more intelligent of the old ones to a hig standard of practice

N EXPLOSIVE OUTBREAK OF Q FEVER

M. G. P. Stoker
M.D. Camb.
LECTURER IN PATHOLOGY, CAMBRIDGE UNIVERSITY

J. F. Thompson
M.R.C.S.
GENERAL PRACTITIONER, WOODCHURCH, KENT

ISOLATED sporadic infections probably account for ost cases of Q fever, but it is well known that severe plosive outbreaks also occur, and indeed their spec- cular nature has often led to the first recognition of the sease in a particular locality. One such outbreak at a ondon hospital in 1949 gave the first definite proof at the disease existed in Great Britain (Harman 1949, acCallum et al. 1949), and, since the source of this utbreak was a fatal case of Q fever from North-East ent (Marmion and Stoker 1950), attention was soon rected to this county, where the disease was discovered be endemic. Many sporadic cases were found (Marmion al. 1953), and in the following year a second outbreak volved 27 students at the Canterbury School of Art. lthough the source of infection was not clearly identified ere, epidemiological evidence suggested that the pening of a packing-case and the removal of straw and ther packing material some nineteen days before the utbreak may have been responsible (Harvey et al. 1951).

This paper describes a third outbreak, distinguished y a remarkably high attack-rate, which took place in eptember, 1951, amongst residents and visitors at a farm n South Kent.

THE OUTBREAK

The farm occupies some 120 acres on high ground verlooking Romney Marsh, and includes a farmhouse, divided into two flats, immediately surrounded by owsheds, a dairy, and pigsties, with two cottages, which ie at the edge of the farm some 250 yards from the house. On land adjoining the farm there is a short row of ouncil cottages, where the two domestic helps at the farm ive; but otherwise the farm is fairly isolated. A dairy herd of tuberculin-tested attested Red Poll cattle and some pigs and poultry form the main business of the farm.

The farmer, Mr. F., and his wife, live on the ground floor of the farmhouse, and a family, comprising Colonel T. (an engineer temporarily home from Kenya), his wife, and two daughters, Maureen and Jill, occupy the upstairs flat. Mr. C., a retired business man, and his wife, who are friends of the farmer, have one of the cottages, and Mr. J. (cowman at the farm) and his wife the other.

On Sept. 1, 1952, Maureen T., aged thirteen, became ill quite suddenly with a headache and fever. Next day her father, Colonel T., who had just returned from five days in Scotland, developed a more severe illness with pneumonia, and he was admitted to Ashford Hospital on Sept. 8. Meanwhile, on Sept. 3, the cowman, Mr. J., became ill, and during the next three days his wife, his neighbour, Mr. C., the farmer himself, his wife, and Colonel T.'s wife also succumbed. By Sept. 7 everyone living on the farm was ill with what was later shown to be Q fever, except for Mrs. C., who did not develop the disease until Sept. 17, and Jill T., aged five, who remained well, but later showed serological evidence of infection. All this came at a busy time, and for a few days there was great difficulty in running the farm; but fortunately many of the illnesses were short and mild.

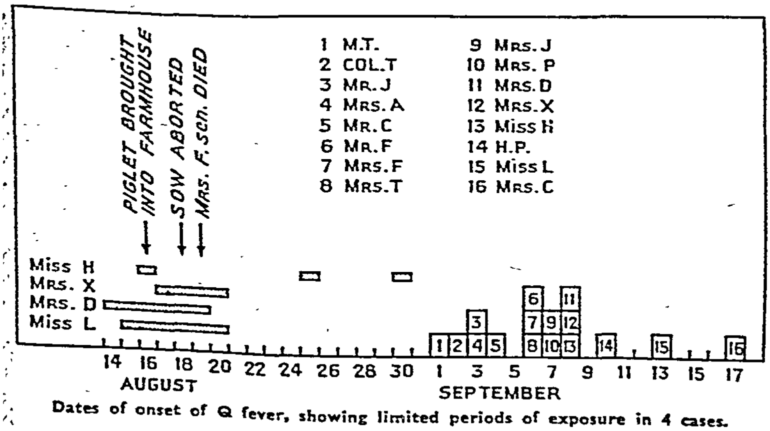
TABLE I—PERMANENT RESIDENTS, TEMPORARY RESIDENTS, AND VISITORS TO FARM FROM AUG. 13 TO 26, 1951

—	Name	Age	Occupation or status	Visits to farmhouse Aug. 13–26, 1951	Onset of Q fever
Living at farmhouse	Mr. F.	48	Farmer	Resident	Sept. 6
	Mrs. F.	32	Farmer's wife	„	Sept. 6
	Mrs. F., sen.	76	Farmer's mother (invalid, died Aug. 19)	„	—
	Mrs. P.	56	Relatives on visit from Berlin (returned Sept. 2)	„	Sept. 7
	Helga P.	8		„	Sept. 10
	Colonel T.	44	Relatives living in upstairs flat	„	Sept. 2
	Mrs. T.	45		„	Sept. 6
	Maureen T.	13		„	Sept. 1
	Jill T.	5		„	—
Living at cottages on farm	Mr. J.	29	Cowman to farm	Daily	Sept. 3
	Mrs. J.	26	Cowman's wife	Aug. 6	Sept. 7
	Mr. C.	45	Retired (friends of farmer)	Frequent	Sept. 4
	Mrs. C.	44		„	Sept. 17
	Mrs. X.	35	Weekend visitors from London (staying with Mr. and Mrs. C.)	Aug. 17–20	Sept. 8
	Bruce X.	10		Aug. 17–20	—
	Miss L.	45		Aug. 15–20	Sept. 13
Visitors to farmhouse	Mr. Y.	58	Casual labourer	Uncertain	—
	Miss H.	42	Friend of Mrs. A.	Aug. 16 and 25	Sept. 8
	Mrs. D.	56	Domestic help	Aug. 14–19	Sept. 8
	Mrs. A.	44	„	Daily	Sept. 3
	Vivienne A.	4	Daughter of Mrs. N.	Daily	—
	Dr. W.	38	Attending Mrs. A., sen.	Aug. 14, 16, 18–20	—
	Dr. V.	51	„	Aug. 20	—
	Nurse N.	46	District nurse	Aug. 13–19	—
	Mr. B.	32	Undertaker	Aug. 20	—
	Mr. Z.	46	„	Aug. 19–20	—

From the dates of onset it seemed likely that infection had taken place sometime in the third week of August. When inquiries were made it was found that there had been 6 extra people living on the farm at about this time (see table I and figure).

Firstly, there had been the farmer's invalid mother (Mrs. F., sen.), who had died of carcinoma of the rectum on Aug. 19. Secondly, his mother-in-law (Mrs. P.) and her granddaughter (Helga P.) had been on a visit from Germany, and they had returned to Berlin on Sept. 2, where they both developed Q fever the following week. Finally 3 visitors from London, Miss L., Mrs. X., and her son Bruce, aged ten, had stayed with Mr. and Mrs. C. at their cottage for a long weekend. Three weeks after their return to London, Mrs. X developed an illness which was assumed to be Q fever on clinical and epidemiological grounds, despite the fact that a specimen of her blood could not be obtained for serological confirmation. Bruce remained well and his serum was not tested, but Miss L. succumbed five days later to a similar illness, and her serum was subsequently found to contain Q fever antibodies.

In addition to the 16 residents, and excluding tradesmen who only made very short visits, 9 other people had visited the farm during the two weeks Aug. 13–26. Miss H., a friend from Rye, spent the afternoons of Aug. 16 and 25 at the farmhouse, and Mr. Y., a casual labourer, worked on the farm. There were two domestic helps (Mrs. D. and Mrs. A.) at the farmhouse, and



Dates of onset of Q fever, showing limited periods of exposure in 4 cases.

red or livid plaques of varying size The lesions were most numerous on the chest and abdomen, and the irritation was unbearable The mucosæ were unaffected

The blood-pressure was 130/90 mm Hg, and X ray examination of the chest showed a normal heart

Laboratory Investigations—Red cells 4,280,000 per c mm, Hb 74%, white cells 5800 per c mm (polymorphs 63%, stab forms 6%, lymphocytes 22%, monocytes 4%, eosinophils 5%), erythrocyte sedimentation rate 108 mm in the first hour (Westergren), blood calcium 9 9 mg per 100 ml, blood cholesterol 224 6 mg per 100 ml The Takata-Ara test was strongly positive The urine was normal Histological examination of the skin showed a non specific inflammatory reaction in the corium with hyperkeratosis We are indebted to Prof Z Kopac, of Sarajevo, for the biopsy report

Treatment and Progress—A diagnosis of herpes gestationis was made The patient was treated with phenobarbitone, antazoline ('Antistin'), and serum from a healthy pregnant woman, but with no success Her condition became desperate, for she was utterly exhausted by the intolerable irritation and lack of sleep, and it was considered justifiable to terminate the pregnancy This was done on April 4, but the disease went relentlessly on

Finally, on April 14, we turned to aureomycin (250 mg every 4 hours) On the second day of treatment she slept better, and the skin lesions became paler and the irritation substantially less On April 21 the aureomycin was stopped because she had severe diarrhœa By that time the skin had cleared except for the legs, where erythema persisted During treatment with aureomycin the eosinophil count rose to 18% on April 16

After aureomycin was stopped, she had vitamin C by mouth and calcium bromide intravenously, but the skin lesions and irritation recurred Starting on April 28 she was given 1 5 g of aureomycin daily for five days On that day the eosinophil count was 6% and the erythrocyte sedimentation rate was 78 mm in the first hour Again the irritation disappeared and the skin lesions subsided On May 5 the eosinophil count was 4% and the sedimentation rate 43 The improvement was maintained and the patient went home on May 9 at her own request She was not completely cured, but she was infinitely better

The association between aureomycin and the improvement in the condition seems clear, but it is hard to see how the drug worked A smaller point which we were also unable to explain was the changing eosinophil count

General Hospital

TIBOR SALAMON

MUMPS ORCHITIS WITHOUT PAROTITIS

SIR,—In his paper last week Mr Connolly describes a case of testicular swelling in an infant and produces convincing evidence that it was due to mumps It is his opinion that many other such cases have the same ætiology, and that mumps more often causes acute swelling of the testicle than does torsion of that organ

My experience, though admittedly of an older age group, convinces me that his conclusions are wrong —that is, unless he considers mumps to be the commonest cause below the age of 1 year and torsion after that age

Of the 13 cases of torsion that I have now seen, 8 were in patients under 14 years, and among the 11 cases I described,[1] 3 of the 5 I had not seen were under 14 years Further, to the best of my knowledge I have seen only 1 child (aged 4) with acute testicular swelling in whom the diagnosis of torsion was not confirmed Although he was admitted with that diagnosis operation was not advised

While appreciating that Mr Connolly advises exploration in all cases of doubt, I would like to add a warning It is not uncommon for the testicle to undergo spontaneous untwisting This occurred in 6 of the 18 cases of which I have notes In 3 operation was performed very shortly after the pain and swelling suddenly subsided In each there was excess fluid in the tunica vaginalis, and congestion of the testicle, as Mr Connolly describes in his second case In 2 of these there was obvious anatomical abnormality, such as a long mesorchium The sudden subsidence of swelling and pain while the testicle was being manipulated was evidence of the mechanical factor.

I suggest, therefore, that unless there is strong evidence of contact with a case of mumps, all such cases should be explored If the testicle is not gangrenous steps should be taken to fix it to the scrotal tissues If the cause of the swelling were torsion its recurrence would thereby be prevented If it were due to mumps no harm would have been done

SUPPORTIVE THERAPY

SIR,—Professor Boyd and his colleagues in their article last week very rightly draw attention to the importance of a rational approach to the development of polymeric substances for use in plasma substitutes No product should be finally accepted until all the recognised important factors have been fully investigated

When more than one such substance is being developed it can always happen that unpublished data are available on one of the polymers which would assist in the assessment of the others, although the ideal molecular [illegible] need not necessarily be the same for every polymer. The results of experimental work on a particular type of polyvinylpyrrolidone, carried out in these laboratories, are being prepared for publication, and some of the conclusions are important in the light of Professor Boyd's paper

I should emphasise that they refer only to the polyvinylpyrrolidone used in 'Plasmosan' In this material the maximum molecular weight is about 100,000 and the peak value about 35,000 Samples of polyvinylpyrrolidone of other molecular weight ranges need not have the same physiological properties as those described here Indeed the differences between the results obtained by us and those on polyvinylpyrrolidone cited by Professor Boyd may easily be accounted for in this way

The excretion of polyvinylpyrrolidone is such that about 40% remains in the body after 24 hours At that time plasma-levels are just less than half of the value immediately after transfusion Detailed interpretation of these results is difficult since the concomitant variation in blood-volume is not known, but they indicate that most of the unexcreted polyvinylpyrrolidone is in the plasma, so that the colloidal osmotic pressure produced can hardly be transient

No histological evidence for the permanent storage of polyvinylpyrrolidone has been found,[1] and this is supported by the following results

Determination of the molecular weight distribution of polyvinylpyrrolidone recovered from the urine of patients receiving intravenous plasmosan has shown that molecules of all the molecular weights present in the infusion are capable of being excreted, and that if a threshold molecular weight exists above which polyvinylpyrrolidone molecules would not be excreted this is considerably in excess of 100,000 The rate of excretion, as would be expected, decreases with increasing molecular weight Consequently, about 14 days after the infusion, when at least 80% of the administered polyvinylpyrrolidone has been excreted, the urine concentration is at the limit of sensitivity of the method of estimation. In but there is no indication that excretion suddenly stops In addition, the residue not accounted for may be excreted by other means—e g, in fæces and sweat—or may possibly be degraded to very small molecules which cannot be estimated by the present experimental methods There is evidence, moreover, in one case studied in great detail, that some such degradation does occur It appears unlikely, therefore, that any appreciable quantity of polyvinylpyrrolidone can remain in the body

e Farm Animals

None of the patients had been bitten by ticks, and re were no sheep or goats on the farm. The most ely source of *R. burneti* was obviously milk, placenta, fæces from one or more of the 12 dairy cows, but the quence of infections among the people on the farm plied that any excretion of organisms by the cows must ve been a new event occurring for the first time tween Aug. 16 and 19. It was therefore surprising to d that nothing unusual had happened in the herd at is time. No new cows had been imported, no calves ere born until Sept. 2, and the same 7 cows had been in ilk for the previous seven months. This milk was used the farmhouse and at one of the cottages. Mr. and rs. C. at the other cottage obtained their milk from a fferent source, but they did occasionally have tea at e farmhouse. The bulk of the milk went to a wholesale iry where it was pasteurised.

Of the 5 cows not in milk, 2 were pastured in a field early two miles from the farm ; 4 of the patients had isited this field on various occasions, but had had no ose contact with the cows.

Various laboratory tests were made on material from e cows during the succeeding months, and the results re shown in tables II and III. We originally intended to ke serum samples from all cows, but foot-and-mouth isease restrictions prevented us doing so. However, it as been shown that there is close correlation between hey and serum antibodies (Stoker and Marmion 1952), nd specimens of whey were eventually tested by the irect agglutination and anti-globulin tests instead. One ow, Dilly, had Q-fever antibodies in her whey, but she as one of the two animals who had been dry and astured in a field two miles from the farm. None of the nimals kept on the farm itself showed any evidence of nfection. The laboratory tests thus support the epidemio-ogical evidence in suggesting that the cows were not esponsible for this outbreak.

There was considerable activity in the piggery during ugust, but although Giroud and Jadin (1951) claim to ave demonstrated Q-fever agglutinating antibodies in igs from the Belgian Congo, these animals have never een shown conclusively to harbour *R. burneti*. Never-heless, it was interesting to learn that two litters of iglets were born at the farm on Aug. 10 and that a sow borted on Aug. 18. One of the piglets was injured by a at, and on Aug. 16 it was brought into the farmhouse or treatment. It was fondled by several individuals who subsequently developed Q fever, including Miss H. who must have been infected on that day or on Aug. 25 see figure). This piglet might have been heavily contami-nated with infected placental fluid from a sow ; so, when he farm was first visited on Oct. 27, sebaceous material was scraped from the piglet's ears and a suspension was noculated into guineapigs and mice ; but *R. burneti* was not isolated. Serum was also obtained from this piglet, from the 3 sows which were delivered in August, nd from 8 other piglets. Pig antibodies are notoriously lifficult to detect by ordinary techniques, and of course positive pig sera were not available for controls ; but the hæmolytic complement-fixation test, the conglutinating complement-absorption test, the direct agglutination test, and the anti-globulin sensitisation test (Coombs and Stoker 1951) all gave negative or non-specific reactions.

As well as the cattle and pigs, there were chickens, ducks, cats, a horse, and a dog on the farm. It was not possible to bleed these animals, but none of them had arrived on the farm in the middle of August.

Other Possible Sources

The body of a patient who has died of Q fever may be highly infective (Marmion and Stoker 1950), and since Mrs. F., sen., died on Aug. 19, there was a possibility that she might have had unrecognised Q fever. On the other hand, there was absolutely no doubt that she died of carcinoma of the rectum with widespread secondary deposits, and there was no evidence of terminal pneumonia. Neither the doctors, the nurse, nor the two undertakers developed Q fever ; and there was no illness at the laundry where the bedding was washed. Another possible source was some furniture and tinned food brought to the farm by Colonel T. from a flat in London which had been vacated after a tenant had died, but this death was later discovered to have been accidental. Lastly, there was a rubbish tip adjoining the farm, but none of the dustmen who used it had been ill at the time of the outbreak.

DISCUSSION

The main interest in this outbreak lies in the very high attack-rate among the people at risk. Of the 15 residents, all the 12 adults and 1 child became ill ; another child may have had a subclinical infection and one (Bruce X.) was not tested. Only 3 of the 9 non-resident visitors developed Q fever, but these were the 3 who probably spent longest in the farmhouse. In fact, with only 1 exception, all the 16 adults who were on the farm for more than brief visits between Aug. 12 and Aug. 26 developed clinical Q fever. The exception was the casual labourer, Mr. Y., whose movements were difficult to trace and who may have been absent at the critical time.

The rate of infection was thus 100% among the residents who were tested and 77% among the total population at risk ; and this is higher than the rate reported for any previous outbreak, except those described by Babudieri (1951) and del Turco et al. (1951) in Italy. It is possible that the individuals at risk were unusually susceptible, but a highly infective strain or the release of unusually large numbers of organisms are more likely reasons for the high attack-rate. It is therefore all the more disappointing that the source of infection was not identified, particularly as the dates of infection were known to within narrow limits. At first sight the cows were certainly the most obvious reservoirs of *R. burneti*, but laboratory tests revealed no evidence of infection in the animals on the farm at the time of infection, and on epidemiological grounds the pigs were far more likely to have been the source, despite the fact that they are not a recognised reservoir of Q fever.

Clinically the outbreak followed a typical course, and it is interesting to note the wide variation in the lengths of the illnesses (the longest being those of the 2 oldest patients) and the rapid response to chloramphenicol.

SUMMARY

In an explosive outbreak of Q fever in South Kent, 13 out of 15 people living on a dairy farm contracted the disease, 1 child had a subclinical infection, and 1 was not tested. There were 3 other cases among 9 visitors to the farm.

Epidemiological findings and laboratory tests did not suggest that the cows were the reservoir of infection. Although there was some evidence pointing to pigs as the source, it was not possible to confirm this in the laboratory.

We are indebted to the owner of the farm and to his wife for their kind coöperation ; to Mr. J. D. Paterson, M.R.C.V.S., of the Veterinary Investigation Centre, Wye, who took the serum specimens from the animals ; to Dr. Krüger, who kindly sent details of his patient from Berlin ; and to Miss Z. Page for valuable technical assistance.

Notes and News

M.R C RESEARCH POSTS

TODAY the Medical Research Council employs nearly 1500 people of these 153 are doctors (or dentists) and a further 286 are science graduates To these workers the council offers an opportunity for a life time career in research comparable to the academic posts available at universities Would be research-workers, especially perhaps those who do not wish to teach, will therefore study with interest the booklet lately compiled by the council which sets out the opportunities for appointment to its scientific staff Some of the research staff work in the council's own laboratories —the largest is the National Institute for Medical Research at Mill Hill—but others are ensconced in M R C units in hospitals and universities throughout the country The council does not appoint staff centrally, but leaves the director of each unit to recommend that a post should be offered to a particular worker For the guidance of candidates the booklet contains a list of these units and a survey of the council's research programme, and candidates are encouraged in the first instance to write to the director of the unit where they would like to work But the council's headquarters staff is always willing to advise the hesitant as to the unit to which they should apply Copies of the booklet, which also sets out conditions of work and terms of service, may be had from the offices of the council, 38, Old Queen Street, London, S W 1

MEDICAL AND DENTAL DEFENCE UNION OF SCOTLAND

Scotland's own medical defence society has now passed its half century, but the latest report on its activities[1] suggests that it is in the full bloom of vigorous youth In its jubilee year, as in previous years, the membership increased, and at Aug 8, 1952, this stood at 7491, compared with 7189 a year earlier The council remarks that, partly owing to the Legal Aid Scheme, cases taken to court have tended to increase, and furthermore " the Courts are inclined more and more to apply the maxim *res ipsa loquitur* " The report draws attention to the need for care in injecting penicillin or other substances, during the year there were several instances in which an injection of penicillin into the buttock affected the sciatic nerve

CANCER RESEARCH IN INDIA

WHILE inaugurating, on Dec 30, in Bombay, the fifth session of the International Cancer Research Commission, India's health minister also opened the Indian Cancer Research Centre, which is the first of its kind in Asia The central government have borne the main part of the cost of erecting and equipping this centre, and have also undertaken to meet the entire costs of maintenance Dr V R Khanolkar, director of the centre, has been appointed president of the International Cancer Research Committee

The meetings of the commission were attended by delegates from more than 20 countries One of the main subjects discussed was the geographical distribution of cancer It was generally felt that there was need for more scientific investigation in the Orient of differences in diet, which apparently gave rise to varied manifestations of the disease

SWIFT'S MALADY

" THE mystery about Swift is that there ever should have been any mystery about him,"[2] Sir Russell Brain remarked in his address to the Royal College of Physicians of Ireland, when they made him a fellow Adroitly disentangling the evidence about this unfortunate genius, he pointed out that, as far as his physical disorders went, Swift suffered for many years from what was undoubtedly Ménière's syndrome, with vertigo and deafness, and later from cerebral arteriosclerosis and involutional melancholia The vertigo first appeared in 1710, just before his 43rd birthday, the deafness came on four years later Many years afterwards he wrote to a friend, " I walk like a drunken man and am deafer than you ever knew me ' He tried many remedies, and it seems many doctors, without deriving the least benefit from either Spa waters made his legs swell and his vertigo worse, which, as Sir Russell remarked, is not surprising in view of the modern treatment of aural vertigo by restriction of fluid intake The syndrome persisted longer with him than is usual, for it afflicted him for most of the rest of his life—and he d[illegible] But there is nothing mysterious about that for the [illegible] was able to outmatch him with a patient who had the [illegible] order for 50 years, and who also was getting distressin[illegible] of vertigo when he was over 70 As for Swift's [illegible] (which he invited his friends to expect by that [illegible] remark about dying at the top), he showed no s[illegible] suggesting mental deterioration till he was over 70, by [illegible] time he was almost completely deaf, and with [illegible] sight, though he refused to wear spectacles At 74 he still writing rational, if depressed, letters, but dur[illegible] following year he had what Sir Russell believes t[illegible] been a cellulitis of the orbit, which was extremely p[illegible] and possibly caused some thrombophlebitis of the s[illegible] petrosal sinus and of the cortical veins draining [illegible] area, for after it he suffered from aphasia Even the [illegible] cousin (confusingly named Deane Swift) reported "S[illegible] times he will not utter a syllable, at other times he will [illegible] incoherent words but he never yet, as far as I could [illegible] talked nonsense, or said a foolish thing " For the [illegible] years of his life he suffered great despondency and [illegible] talked at all He is said to have died after conv[illegible] lasting 36 hours, and a post-mortem examination [illegible] " much water on the brain "—a likely enough accomp[illegible] of arteriosclerotic atrophy His last bust suggests a r[illegible] palsy, which might well accompany a lesion of Broca's [illegible]

Swift's emotional disorder, displayed in his relation[illegible] Stella, is, Sir Russell suggested, equally devoid of [illegible] " He was a single man of irreproachable morals, [illegible] woman for years and he did not publicly marry her " I[illegible] he did marry her, privately, but if so it makes little di[illegible] to the story He had, Sir Russell thinks—and he s[illegible] the idea with satisfactory evidence—an obsessional pers[illegible] emotionally arrested at an immature level of develop[illegible] A common enough state but in Swift it was combined [illegible] intellectual genius In attempting to reconcile the [illegible] and the emotions, each of us engages in a daily bal[illegible] feat, when the two are widely disparate in their d[illegible] ment the feat becomes impossible, and the unfort[illegible] subject suffers accordingly Swift's emotional immatur[illegible] made married life impossible to him, but he could g[illegible]

" Friendship in its greatest Height
A constant rational Delight '

(an offer made, in fact, not to Stella but Vanessa) Merci[illegible] for him, Stella was able to accept it, though Vanessa wa[illegible]

NEW AUSTRALASIAN RESEARCH FUND

THE Life Offices' Association for Australasia has establ[illegible] a fund to promote scientific and medical research in Au[illegible] and New Zealand Announcing this, the *Medical Jo[illegible] of Australia* (Jan 3) says that about £25,000 per annu[illegible] likely to be spent, sums will be payable either as gr[illegible] in-aid or for research fellowships To begin with, the [illegible] will be used to foster research in cardiovascular diseases.

FILM ON CONTROLLED HYPOTENSION

A NEW film on the reduction of surgical hæmorrhag[illegible] controlled hypotension was shown at the Royal Colle[illegible] Surgeons, London, on Jan 8 This film, produced by M[illegible] May & Baker Ltd, is in colour with sound, and is inte[illegible] primarily for anæsthetists

A brief introduction on the desirability of reducing sur[illegible] hæmorrhage is followed by an animated sequence illustra[illegible] the factors affecting blood flow and blood pressure T[illegible] principles of ganglionic transmission and paralysis are [illegible] lined, and the action of the more usual ganglion paraly[illegible] such as tetraethylammonium bromide, procaine, nicotine, [illegible] hexamethonium bromide, is demonstrated The cli[illegible] section shows in detail the use of hexamethonium bromide [illegible] bring about controlled hypotension and, by suitable positi[illegible] of the patient, postural ischæmia for hemiresection of [illegible] mandible and block dissection of the glands of the [illegible] Further operations illustrate the main benefits from [illegible] technique these include shortened operation time, clear [illegible] vision in difficult operation fields, reduction in the numb[illegible] operations necessary for a particular patient, and some[illegible] reduction of total blood loss

The film was introduced by Sir Cecil Wakeley, P[illegible] Sir Archibald McIndoe emphasised that it dealt prim[illegible] with an anæsthetic technique which was of great valu[illegible] surgery, and particularly to plastic surgery He ad[illegible] however, that this technique should be used only experienced anæsthetists

* * *

We medical dons are sometimes envied by the more cessful members of the profession, the real doctors. nice quiet life, they say, for we have it in malt if not [illegible] olidays, of course. True, academic [illegible] he systole of terms with diastoles tween. But what they forget is that for many of us that the vacation means is no lectures, which are er all only a small item of the academic daily round. nmarked examination papers, unfinished research, read proofs still await us: the library committee still eets, and autopsies, on mice or men, go on as usual. And to get down to details, what can anyone make of a nuary holiday? There's Madeira and Marrakeesh, but e can do those only by brochure. I have slithered lf-frozen on the hills, and stumbled over upturned boats the winter darkness of famous promenades. The aster vacation is little better. It is too early for omfort, and in the country your only friend is the lesser elandine. But give me June, Mr. Vice-Chancellor, and ll show you what I can do. He won't, though. Instead, e gives us the heaviest examinations of the year—final onour schools—and students and examiners both weat away in the first heat-wave. July and August nd us still hard at it, for colleagues also need a rest. And so it's September, as often as not truly backendish—histling winds, heavy rain, leaves flying, and officially oo early for fires. No wonder the session starts off with olds and influenza. But October, when the equinoctial ales are over, is often rich in sunshine. By this time, owever, we are up to the neck again—coping with the ew class, addressing the medical societies, and longing or our January break . . .

* * *

She was describing some small brown mobile objects which had been present in her little boy's urine. "I was very stupid at first, doctor," she said, "because I thought they were tea leaves, but now I've just remembered he doesn't drink tea."

* * *

He belonged to a well-known local family of gipsies, and was suffering from lobar pneumonia, after a night spent in a drunken stupor in a cold, damp ditch. I took appropriate action, and he made a rapid recovery. Later when I pointed out to him the probable ætiological significance of his night's exposure, he asked me whether I would allow him to go into the pub at night, to have just one or two beers, as this was an essential part of his job. When I asked for further details he explained that the greater part of his income came from the buying and selling of lead, and the trading was done in the local. So yet another disease is shown to be connected with this unhappy metal.

Driving back that night I mused on the changing pattern of industrial disease. Will the decreased incidence of Crystal-Gazer's Strabismus and Palmar Argyria be counterbalanced by an increase in Lead-Merchants' Pneumonia and Truncheon Coma? Has the gipsy laid down his fiddle to take up another?

* * *

The Physiologists have long been discouraging about alcohol as a restorative after exposure to cold, and the *Medical Journal of Australia*[1] has lately had harsh things to say about St. Bernard dogs and their flasks of brandy. Alcohol causes the skin blood-vessels to dilate, thereby diverting the warmed blood from the more essential inner organs to the surface of the body where it is promptly cooled. So the *Journal* advises the dogs to carry 'Thermos' flasks of hot milk instead. But of course Sydney is a very long way from Switzerland.

Letters to the Editor

PRECISION IN DIAGNOSIS

SIR,—Dr. Todd is always stimulating; he manages to put on paper what most of us only ponder on.

Diagnosis literally means knowing through and through: it is the very fullest statement of every aspect of a case. Of course we always use it to mean the exact reverse; it is the shortest possible summary, the label. So let it be. Medicine has little respect for the classics.

A label is a useful thing. Rightly affixed it gets one to one's destination. Wrongly addressed it can misdirect one seriously. The practical exigencies of medicine will always require such labels. We should make them reflect reality as accurately as possible. To that end I enter a plea for the "serial" diagnosis.

Those of us who do general practice in any form know that it is only a tiny minority of illnesses that can be adequately and honestly covered by a single term like "mastoiditis" or "intussusception." The case has actually carried a series of labels, such as "upper respiratory infection," "N.A.D. earache," "otitis media," "mastoiditis for admission," "recent mastoidectomy"; or instead "collywobbles," "colic with constipation," "intestinal obstruction," "intussusception at operation," "stitch abscess." Which one of these the records officer chooses to select for his returns is of little importance. Each in its time has been the correct diagnosis. Case-records both for general practice and for hospitals should be designed with that in mind. Instead of a ridiculous little box in the top corner, one should have space for half a dozen insertions with their dates.

A wider appreciation of the practical inevitability of serial, rather than single, diagnoses would in my view lessen the need knowingly to invoke phoney pathology, such as the usual "fibrositis," "neuritis," or "gastritis." All diagnoses are temporary; most are tentative. A large number of complaints met in general work never need carry their series of labels as far as the pathological diagnosis. They resolve spontaneously or are of such a nature that the labours and sufferings entailed in going further are not warranted by the prospects of clinical improvement. For such cases it may be that a new category of accepted terms could come into use. How about undifferentiated somatic pain ("U.S.P.") or acute undifferentiated abdominal pain ("A.U.A.P.")? "Lumbago" takes a lot of beating! Such phrases, having no insidious implication of finality, leave the mind open to revise and review, which is surely what serves the patient best. Diagnostic labels should reflect the harassed uncertainty of the clinician, not the euphoric naivety of the morbid histologist.

Student Health Association,
University College,
Gower Street,
London, W.C.1.

NICOLAS MALLESON.

SIR,—Many of the truths and criticisms expressed in the thoughtful article by Dr. Todd (Dec. 27) must of course be admitted; but is the fact that attempts at precision in diagnosis can be overdone sufficient reason for relaxing effort towards that end? His arguments are so forceful as almost to persuade one of the necessity for a return to Hippocratic principles in diagnosis, with their emphasis on description of the patient and his ills.

In reply to Dr. Todd's question "Do not such homely phrases as 'depressed and worried about himself' and 'stupid and self-centred' often give a better understanding of the symptoms?" one feels impelled to answer "No." These are mere descriptive terms the pronouncement of which would not warrant a long, arduous, and expensive professional training. The description of a patient as "stupid" hardly argues understanding in the physician. Secondly, the effort of assessing the significance of a symptom such as

Notes and News

M.R C RESEARCH POSTS

TODAY the Medical Research Council employs nearly 1500 people of these 153 are doctors (or dentists) and a further 286 are science graduates To these workers the council offers an opportunity for a life time career in research comparable to the academic posts available at universities Would be research-workers, especially perhaps those who do not wish to teach, will therefore study with interest the booklet lately compiled by the council which sets out the opportunities for appointment to its scientific staff Some of the research staff work in the council's own laboratories —the largest is the National Institute for Medical Research at Mill Hill—but others are ensconced in M R C units in hospitals and universities throughout the country The council does not appoint staff centrally, but leaves the director of each unit to recommend that a post should be offered to a particular worker For the guidance of candidates the booklet contains a list of these units and a survey of the council's research programme, and candidates are encouraged in the first instance to write to the director of the unit where they would like to work But the council's headquarters staff is always willing to advise the hesitant as to the unit to which they should apply Copies of the booklet, which also sets out conditions of work and terms of service, may be had from the offices of the council, 38, Old Queen Street, London, S W 1

MEDICAL AND DENTAL DEFENCE UNION OF SCOTLAND

Scotland's own medical defence society has now passed its half century, but the latest report on its activities[1] suggests that it is in the full bloom of vigorous youth In its jubilee year, as in previous years, the membership increased, and at Aug 8, 1952, this stood at 7491, compared with 7189 a year earlier The council remarks that, partly owing to the Legal Aid Scheme, cases taken to court have tended to increase, and furthermore "the Courts are inclined more and more to apply the maxim *res ipsa loquitur*" The report draws attention to the need for care in injecting penicillin or other substances, during the year there were several instances in which an injection of penicillin into the buttock affected the sciatic nerve

CANCER RESEARCH IN INDIA

WHILE inaugurating, on Dec 30, in Bombay, the fifth session of the International Cancer Research Commission, India's health minister also opened the Indian Cancer Research Centre, which is the first of its kind in Asia The central government have borne the main part of the cost of erecting and equipping this centre, and have also undertaken to meet the entire costs of maintenance Dr V R Khanolkar, director of the centre, has been appointed president of the International Cancer Research Committee

The meetings of the commission were attended by delegates from more than 20 countries One of the main subjects discussed was the geographical distribution of cancer It was generally felt that there was need for more scientific investigation in the Orient of differences in diet, which apparently gave rise to varied manifestations of the disease

SWIFT'S MALADY

"THE mystery about Swift is that there ever should have been any mystery about him,"[2] Sir Russell Brain remarked in his address to the Royal College of Physicians of Ireland, when they made him a fellow Adroitly disentangling the evidence about this unfortunate genius, he pointed out that, as far as his physical disorders went, Swift suffered for many years from what was undoubtedly Ménière's syndrome, with vertigo and deafness, and later from cerebral arteriosclerosis and involutional melancholia The vertigo first appeared in 1710, just before his 43rd birthday, the deafness came on four years later Many years afterwards he wrote to a friend, "I walk like a drunken man and am deafer than you ever knew me' He tried many remedies, and it seems many doctors, without deriving the least benefit from either Spa waters made his legs swell and his vertigo worse, which, as Sir Russell remarked, is not surprising in view of the modern treatment of aural vertigo by restriction of fluid intake The syndrome persisted longer with him than is usual, for gid[illegible] afflicted him for most of the rest of his life—and he d[illegible] But there is nothing mysterious about that for the [illegible] was able to outmatch him with a patient who had the [illegible] order for 50 years, and who also was getting distressing [illegible] of vertigo when he was over 70 As for Swift's [illegible] (which he invited his friends to expect by that [illegible] remark about dying at the top), he showed no [illegible] suggesting mental deterioration till he was over 70, by [illegible] time he was almost completely deaf, and with [illegible] sight, though he refused to wear spectacles At 74 he [illegible] still writing rational, if depressed, letters, but dur[illegible] following year he had what Sir Russell believes to [illegible] been a cellulitis of the orbit, which was extremely pa[illegible] and possibly caused some thrombophlebitis of the sup[illegible] petrosal sinus and of the cortical veins draining B[illegible] area, for after it he suffered from aphasia Even the [illegible] cousin (confusingly named Deane Swift) reported "[illegible] times he will not utter a syllable, at other times he will [illegible] incoherent words but he never yet, as far as I could [illegible] talked nonsense, or said a foolish thing" For the la[illegible] years of his life he suffered great despondency and h[illegible] talked at all He is said to have died after convul[illegible] lasting 36 hours, and a post mortem examination re[illegible] "much water on the brain"—a likely enough accompa[illegible] of arteriosclerotic atrophy His last bust suggests a ri[illegible] palsy, which might well accompany a lesion of Broca's [illegible]

Swift's emotional disorder, displayed in his relation[illegible] Stella, is, Sir Russell suggested, equally devoid of [illegible] "He was a single man of irreproachable morals, [illegible] woman for years and he did not publicly marry her' [illegible] he did marry her, privately, but if so it makes little d[illegible] to the story He had, Sir Russell thinks—and he [illegible] the idea with satisfactory evidence—an obsessional pers[illegible] emotionally arrested at an immature level of develop[illegible] A common enough state but in Swift it was combined [illegible] intellectual genius In attempting to reconcile the in[illegible] and the emotions, each of us engages in a daily bal[illegible] feat, when the two are widely disparate in their de[illegible] ment the feat becomes impossible, and the unfortu[illegible] subject suffers accordingly Swift's emotional immat[illegible] made married life impossible to him, but he could give

" Friendship in its greatest Height
A constant rational Delight '

(an offer made, in fact, not to Stella but Vanessa) Men[illegible] for him, Stella was able to accept it, though Vanessa was [illegible]

NEW AUSTRALASIAN RESEARCH FUND

THE Life Offices' Association for Australasia has establ[illegible] a fund to promote scientific and medical research in Au[illegible] and New Zealand Announcing this, the *Medical Jo[illegible] of Australia* (Jan 3) says that about £25,000 per annu[illegible] likely to be spent, sums will be payable either as g[illegible] in aid or for research fellowships To begin with, the [illegible] will be used to foster research in cardiovascular disease[illegible]

FILM ON CONTROLLED HYPOTENSION

A NEW film on the reduction of surgical hæmorrhag[illegible] controlled hypotension was shown at the Royal Colleg[illegible] Surgeons, London, on Jan 8 This film, produced by Mes[illegible] May & Baker Ltd, is in colour with sound, and is inte[illegible] primarily for anæsthetists

A brief introduction on the desirability of reducing sur[illegible] hæmorrhage is followed by an animated sequence illustra[illegible] the factors affecting blood flow and blood pressure [illegible] principles of ganglionic transmission and paralysis are [illegible] lined, and the action of the more usual ganglion paraly[illegible] such as tetraethylammonium bromide, procaine, nicotine [illegible] hexamethonium bromide, is demonstrated The cl[illegible] section shows in detail the use of hexamethonium bromid[illegible] bring about controlled hypotension and, by suitable positi[illegible] of the patient, postural ischæmia for hemiresection of [illegible] mandible and block dissection of the glands of the [illegible] Further operations illustrate the main benefits from [illegible] technique these include shortened operation time, clar[illegible] vision in difficult operation fields, reduction in the numb[illegible] operations necessary for a particular patient, and some [illegible] reduction of total blood loss

The film was introduced by Sir Cecil Wakeley, P[illegible] Sir Archibald McIndoe emphasised that it dealt pri[illegible] with an anæsthetic technique which was of great valu[illegible] surgery, and particularly to plastic surgery He ad[illegible] however, that this technique should be used only [illegible] experienced anæsthetists cases after cortisone and the subcortical hæmor- s in the fatal case, I am of the opinion that cortisone responsible for the convulsive episodes in all these . I think that cortisone is contra-indicated in infection, where the mobilisation of the defensive reparative mechanisms of the body are all-important. ture I certainly shall not use cortisone in meningitis its rôle is more clearly established.

dney, Australia. BRIAN HAYNES.

ATION OF THE POPLITEAL VEIN FOR THE GRAVITATIONAL SYNDROME

IR,—Mr. Goligher, in his interesting remarks last k about ligation of deep veins for valvular incom- ence, makes the assumption that ligation of either the erficial femoral or popliteal veins will have the same sequences as far as the venous circulation in the lower is concerned.

t is possible, however, that a resistance placed at the let of the calf-muscle pump (which is presumably at ligation of the popliteal vein amounts to) would be re efficient in diminishing reflux during calf diastole n one placed at the groin with a considerable venous ervoir intervening. Further, the resistance offered the two procedures is probably not the same; the n profunda femoris vein provides a by-pass of much ger calibre than any at the knee after popliteal vein ation.

In support of this hypothesis is the finding[1] that pliteal vein ligation in patients with incompetent lves in the deep veins of the leg can reduce the high nous pressure in the foot, measured during exercise, ich exists in such patients. Comparable hydrostatic [illegible] has not, to my knowledge, been shown for e superficial femoral vein.

I do not wish to advocate popliteal vein ligation, but lieve it cannot justifiably be condemned because ation of the superficial femoral vein does not succeed.

niversity College Hospital Medical
School, London, W.C.1. C. J. LONGLAND.

THE SURGICAL TREATMENT OF ULCERATIVE COLITIS

SIR,—I do not wish in any way to detract from the erits of the excellent article on this subject by Mr. ounsell and Mr. Goligher (Nov. 29); but I feel that, ough ileostomy is no doubt often necessary in ulcerative olitis where medical treatment fails, there is still a lace for the older operation of appendicostomy, at least s a trial before resorting to the more serious and utilating one of permanent ileostomy, coupled with olectomy with its mortality of 16%.

Appendicostomy was at one time regarded as a good peration; it clearly cannot succeed if there are ulcers bove the colon, but I feel that this is possibly the xception rather than the rule. The operation fell into isrepute because of Arthur Hurst's dogmatic statement hat lavage of the colon from below is just as effective s lavage with 4 pints of saline through an appendicostomy pening, but I doubt if this is necessarily always so.

Ulcerative colitis is rare in children, in whom it was irst described by Helmholtz at the Mayo Clinic as late s 1923. As a pædiatrician, I can only recollect having een two examples in the last ten years or so, both, of ourse, in older children.

The first of these was not doing entirely satisfactorily after a year of medical treatment; and, being aware of the danger of carcinomatosis supervening even in an older child or young adult (probably about 10% according to American figures), I approached Mr. Henry Stokes with the request that he should do an ileostomy. Even under considerable pressure from me, he held out in his view that an appendicostomy should be tried first. The child washed her colon out daily for a year; and when, after a further trial period of three months during which lavage was suspended, the stools remained normal the appendicostomy was closed. The radiographic appearances returned from the typical "ironed-out" and "string" pattern to the normal one with its characteristic haustrations; and the patient has remained perfectly well for five years. When I saw her recently, she told me that she is now a typist.

The second case, a boy, has done very well so far with an appendicostomy, again after a period of medical treatment had failed. He now has relatively normal stools free from blood, and he has put on 10 lb. in weight since his operation in June.

What applies to a child may not necessarily apply to an adult; but at least one cannot help feeling that this girl's future is likely to be a happier one, from a marital and every other point of view, with a normal body such as she has than with a permanent ileostomy.

National Children's Hospital,
Dublin. R. E. STEEN.

THERAPEUTIC APPLICATION OF PLASMA CHOLINESTERASE

SIR,—Dr. Barnard's letter (Dec. 13) is of great interest, and now that succinylcholine chloride is widely used in anæsthesia the confirmation that plasma "pseudo"-cholinesterase concentrate is an effective and innocuous antagonist of the drug is encouraging. Dr. Barnard says, however, that "some of the observed therapeutic effects . . . remain inexplicable." The same can sometimes be said of the anticholinesterase, neostigmine.

The danger of giving such a cholinesterase inhibitor in the presence of succinylcholine (cholinergic) paralysis is supported by substantial experimental and theoretical evidence. Several writers[1–5] have mentioned the prolongation produced by neostigmine, a powerful inhibitor of the cholinesterase which is responsible for the hydrolysis of succinylcholine. Three cases of paralysis apparently prolonged in this way have been published,[6–8] but Grant[9] described a case in which paralysis persisting until the third day after 80 mg. of succinylcholine was reversed by 1·0 mg. of neostigmine. Ruddell[10] had success with 6·0 mg. of neostigmine in a patient who had had succinylcholine and decamethonium. Other cases have been reported after decamethonium.

The following report tells of another instance in which neostigmine was used successfully.

A woman of 62, weighing 120 lb., had malæna due, it was thought, to a peptic ulcer. 2 pints of packed red cells raised her hæmoglobin from 39 to 62%. Her general condition was fair, and the blood-pressure was 120/90 mm. Hg. She was operated on after a second 2 pints of packed red cells.

Premedication.—Pethidine 100 mg. and atropine gr. $^1/_{100}$.

Induction.—Thiopentone 0·25 g. and succinylcholine chloride 25 mg., followed by intubation.

Maintenance and Progress.—Nitrous oxide and oxygen (65/35%) at 6 litres per min. on semi-open circuit with absorption. Intermittent pethidine (total 50 mg.). Full spontaneous respirations returned before the peritoneum was opened. Thiopentone (0·25 g.) and *d*-tubocurarine (10 mg.) sufficiently relaxed the poorly developed abdominal wall, though adequate respirations remained.

Laparotomy, lasting 35 min., revealed an inoperable carcinoma. For closure, 25 mg. of succinylcholine produced immediate apnœa and relaxation, but unforeseen surgical difficulties led to some delay and closure took 55 min. Relaxation was continued by small doses of succinylcholine, given when weak respiratory efforts reappeared (total 225 mg.).

When controlled respiration was stopped feeble inadequate diaphragmatic respirations returned, but there was no inter-

Award for Research on Infertility

The American Society for the Study of Sterility is offering a prize of $1000 for an essay on infertility and sterility Essays must be submitted not later than March 1, 1953, and further particulars may be had from Dr Herbert H Thomas, assistant secretary of the society, 920 South 19th Street, Birmingham, Alabama

British Council for Rehabilitation

On Wednesday, Feb 4, at the Royal College of Nursing, Henrietta Place, London, W 1, the council is to hold a conference on Speeding Recovery Through the Closer Cooperation of Hospitals and Industry Particulars may be had from the general secretary, at Tavistock House (South), Tavistock Square, W C 1

William Gibson Research Scholarship for Medical Women

The Royal Society of Medicine will make the next award of this scholarship (£200 p a) in July It is open to women doctors who are subjects of the British Empire, and it is usually tenable for two years Further particulars may be had from the Secretary of the Society, 1, Wimpole Street, London, W 1, to whom applications should be sent not later than June 1

A Blood-donor Marathon

Last weekend Montreal had a "blood donor marathon" The *Times* (Jan 12) reports that this started on Saturday morning and continued until midnight on Sunday, and the blood collected was expected to total 1850 pints The Ex-Service Men's Taxi Association provided free transport for donors, and entertainers gave their services in a non stop variety show It was expected that by the end of the marathon 6000 more people would have promised to give blood at a future date

ALMONERS

ɪR,—I fully endorse the last paragraph of your otation on Almoners (Dec. 27) which says: "It would ly be better, as a first step, to consider the factors ch are hindering recruitment of almoners of our sent high standard." Some of these factors are ıtioned earlier, and to these should be added the fact, hasised in the Cope Committee's report on almoners, t there are too few students in social science in the versities to meet the requirements of all professions which this training is the basis, and until this shortage be overcome there does not seem any likelihood of viding adequate numbers of almoners.

t is, therefore, of paramount importance that ioners should be employed only on the medical social rk for which their course of training especially equips m. Any dissipation of their energies to cover administive and clerical duties, such as registration, appointnts, waiting-lists, and transport arrangements, is steful and can only lead to a proportionate lessening of ir value as almoners. Some hospitals have taken a long ie to grasp the value and proper uses of almoners. ıers, regrettably, have not grasped these points yet. e limited number of almoners could be distributed r a much larger number of hospitals if they were all owed to concentrate on medical social work. This in elf is no narrow, restricted field but, according to a ent definition, consists in studying the patient's social ckground and his reactions to illness with a view to isting in the solution of the many personal and ıctical problems which are associated with illness.

The members of the Institute of Almoners have ently been reconsidering this problem in order to see w the available medical social skill can be employed ere it will be best used for furthering the patient's erests. It is understood that they hope shortly to omit a memorandum on this subject to the Minister Health. Meanwhile it cannot be too strongly emphaed that an obvious and immediate way of alleviating present shortage problem is to ensure that almoners engaged only on almoner's work.

FRACTURES OF THE NECK OF THE FEMUR

SIR,—With reference to my recent article on a techque for inserting the Smith-Petersen nail for fractures the neck of the femur without moving the patient m his bed,[1] it has been brought to my notice that of. Carl Semb, of Oslo, published a paper in 1938[2] scribing his own technique, which was also designed relieve the patient of disturbance and shock by rrying out all the treatment, including operation, in e patient's own bed.

Although his technique is quite different from my own, e principle is the same. In a personal communication tells me that his method has now been used in over a ousand cases in his department, with excellent results. hat is more important is that he states that this method, cause it is less liable to cause shock, enables him to erate in 90% of cases.

As I emphasised in my paper, the avoidance of shock using a simple technique and avoiding all disturbance the patient makes the operation a life-saving measure as well as a means of treating the fracture. I would like to draw the attention of all those who have to deal with these cases to Professor Semb's paper.

Guy's Hospital, London, S.E.1. T. T. STAMM.

AGRANULOCYTOSIS DURING ISONIAZID THERAPY

SIR,—Dr. Ferguson (Dec. 13) describes a patient with an agranulocytosis whose blood-count promptly returned to normal after cessation of treatment with isoniazid. In this connection the following case is of interest.

A patient, aged 20 years, suffering from diabetes mellitus and pulmonary tuberculosis, received: (1) streptomycin 1 g. daily from Nov. 3 to 20; (2) *p*-aminosalicylic acid (P.A.S.) 12 g. daily from Nov. 3 to Dec. 12; (3) isoniazid 200 mg. daily (3 mg. per kg. body-weight) from Nov. 21 to Dec. 12.

On Dec. 10 he developed fever, followed next day by slight jaundice. The liver was slightly enlarged, but the spleen was not felt. The urine contained bile pigments.

A blood-count on Dec. 10 showed an agranulocytosis. Next day, after all treatment was stopped, sternal puncture showed a maturation arrest at promyelocyte level with a considerable reduction of the number of neutrophil semi-mature myelocytes and complete absence of neutrophil myelocytes and polymorphs.

The details of the sternal-marrow count were:

	Percentage
Neutrophil (segmented)	0
„ (myelocyte)	0
„ (semi-mature myelocyte)	0·5
„ (semi-mature myelocyte in mitosis)	0·25
„ (promyelocyte)	3·0
„ (promyelocyte in mitosis)	0·25
Eosinophil (segmented)	0·75
„ (promyelocyte)	0·25
Myeloblast	1·75
Lymphocyte	8·5
Monocyte	3·75
Promonocyte (? promyelocyte)	2·0
Monoblast (? myeloblast)	2·75
„ (in mitosis)	0·25
Normoblast (orthochromatic or late polychromatic)	36·25
„	18·0
„	0·75
„	5·5
„	0·25
Proerythroblast	0·5
Hæmocytoblast	0·25
Megakaryocyte	0·5
Reticulum cell (macrophage)	5·5
„ plasma cell	1·75
„ lymphoid cell	6·75

There was an increased proportion of monocytes in the peripheral blood throughout the whole agranulocytic episode.

The patient was given penicillin, pyridoxine, aureomycin, and methionine. The temperature (104°F on Dec. 12) fell by lysis, and six days after stopping P.A.S. and isoniazid the granulocytes started to reappear and the fever finally disappeared.

The changes in the differential white blood-cell count are shown in the accompanying table. Hæmoglobin red cells, reticulocytes, and platelets were normal throughout.

DIFFERENTIAL WHITE BLOOD-CELL COUNTS

Date	White cells per c.mm.	Neutrophils (%)				Eosinophils (%)	Basophils (%)	Monocytes (%)	Lymphocytes (%)

2. Semb, C. *Surgery*, 1938, 4, 321.

given, usually producing a stool of 150–200 g with a very low electrolyte content Fæcal losses were therefore ignored As no patient was febrile, except for a short time after operation, sodium and chloride losses in sweat were also ignored In calculating the balances 30 m eq was considered a reasonable allowance for losses of sodium and chloride in the operating theatre

Nearly all the patients were weighed every day, always in the first 2 hours of the period, with the bladder empty, by the same observer using the same scales (Avery, model 1064) Observations could easily be made to within 4 oz, as shown by multiple readings The weight of the dressings (a strip of gauze and plaster) was negligible While on intravenous fluids the patients received no protein and not more than 600 calories in 24 hours (glucose 150 g) during this time, therefore, they would be expected to lose about 1 lb in weight and some 30 m eq of sodium per 24 hours (Gamble 1951)

Results

Our results show that three separable phases of retention can be recognised after operation We have named these primary water retention, early sodium retention, late sodium retention

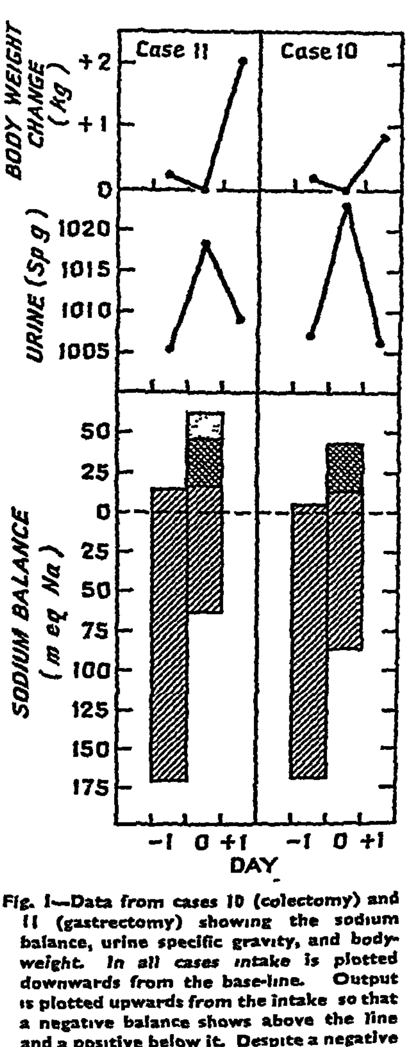

Fig. 1—Data from cases 10 (colectomy) and 11 (gastrectomy) showing the sodium balance, urine specific gravity, and body-weight. *In all cases intake is plotted downwards from the base-line.* Output is plotted upwards from the intake so that a negative balance shows above the line and a positive below it. Despite a negative sodium balance on the day of operation these patients showed the weight-gain of primary water retention

▨ URINE
☐ GASTRIC SUCTION
▩ ALLOWANCE FOR SODIUM LOSS DURING OPERATION

Key to figs 1 3 4 and 5

Primary Water Retention

15 patients were weighed on the morning after operation Every one showed a gain in weight of 1 8–5 1 lb (0 8–2 3 kg), the average being 3 3 lb (1 5 kg) (see table I) This occurred when the calorie intake in the 24 hours was less than 600 calories, was accompanied by oliguria with a raised specific gravity (see table I), it can only have been due to water retention, which was never less than 1 litre This water retention is not due to gastrectomy in itself, nor to the change from oral to intravenous fluids, as cases 10 and 21 show These 2 patients underwent respectively colectomy and herniorrhaphy, the latter receiving oral fluids throughout, yet both showed water retention with characteristic urine changes

In 4 patients (cases 10–13) no sodium was given on the day of operation (save for that in a bottle of citrated blood) The data from cases 10 and 11 are summarised in fig 1, which shows that the weight-gain and high urinary specific gravity occurred despite a ne sodium balance It is evident, therefore, th retention is the primary event This is conf the changes in the plasma-protein and ele concentrations, which indicate dilution of the and extracellular fluid on the day after op (table II)

TABLE II—AVAILABLE FIGURES SHOWING BLOOD CHANGES DURING THE 24 HOURS AFTER OPER.

Case no	Plasma Na (m eq per litre)		Plasma Cl (m eq per litre)		Plasma (g per
	0	0+1	0	0+1	0
2	158	146	112	103	[illegible]
3	144	146	104	99	65
4	155	140	102	94	68
5			109	102	[illegible]
7	142	138	110	105	65
9	150	138	102	100	[illegible]
10	144	144	100	99	63
11	144	136	107	94	67
14	152	144	106	101	[illegible]
15	144	136	100	94	67
16	146	142	102	96	70
18	142	142	95	90	63
21	138	132	103	103	68

In case 10 (colectomy) urine samples were 4-hourly from the indwelling catheter The information obtained is summarised in fig 2, show for nearly 24 hours the urine flow was reduced, specific gravity and chloride concentration the characteristic effects of the release of anti- hormone, and we know of no other physiological nism that produces such a result In only 2 p (cases 1 and 18) was this action prolonged second postoperative period; in all the others, day, the urine specific gravity was below 1 010, and was an increased volume of urine of low sodium chloride concentrations In many cases there was same time a loss of part or all of the weight by water retention on the day of operation, thou some th masked further and water r tion

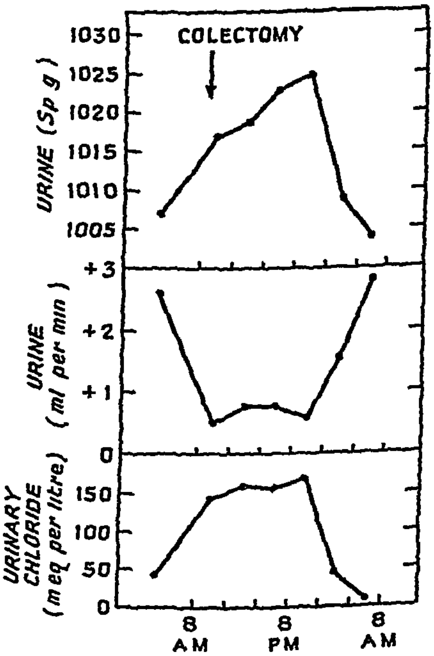

Fig 2—Data from case 10 The first observations were made on the pooled 24-hour specimen for the day preceding operation thereafter 4-hourly specimens were examined The results show the prolonged fall in urine volume and the rise in specific gravity and chloride concentration

Early Sod Retention

The 17 p given sod during the operation showed a po balance for period Lea aside cases 9 21, with a l intake, the r for the o was 70–186 m (average 10 some cases or all of retained sod was excret the next (fig 3)

Coincidin it does wi water retent this early sod retention accompanied a urine of to have removed from the register all who failed to conform modern standards before new ones had been trained would ve created chaos: to have been too lenient and weak would ve failed to bring home to the profession the necessity of provement if they were to retain their registration. Above it was necessary to improve the tests of general education the candidates, to increase the training and, to stiffen the ndards of the examination. Only in this way could a ofession be created which would attract candidates from a her social scale with greater intelligence and better ucation. That this was done gradually without chaos and ith the minimum of friction was due in no small measure the firmness, patience, and breadth of vision of the first hairman of the board, Sir Francis Champneys.

Needless to say the new supervisor of midwives and myself on fell foul of each other when she reported some of my idwives to the board; but soon I realised that the power iven to this board was being exercised with firmness tempered ith common sense and understanding and that the supervisor as encouraged to train rather than to punish. When I ecame conscious of this influence at the highest level I, and obably all others in similar posts, freely coöperated with the upervisor to the great advantage of the midwives and of the ervice. Of all my staff only one had her name removed om the register, and she thoroughly deserved it, though many were reported to the board, admonished by the chairman, and dismissed with a caution, always with good effect.

During the chairmanship of Sir Francis Champneys his despised profession of poorly educated, poorly rained women, grew into the profession as we know it oday. Gradually the period of training and the standard f general education and examination were raised, and with each step a better class of woman was attracted to he service, until now it is one of which the members ere justly proud and with its own college.

This indeed is a fitting memorial to the wise guidance f Sir Francis Champneys through the 28 years of his hairmanship. As there can be few, if any, alive today who saw at such close quarters the work of the C.M.B. nd its chairman, I feel that I must put on record what his service owes to him.

CHRONIC BRONCHITIS AND BRONCHIAL CARCINOMA

SIR,—During recent hospital experience I have been greatly impressed by the autopsy findings in a number of patients dying after long-continued chronic bronchitis and emphysema. These autopsies confirmed our clinical opinion that death had resulted from terminal bronchopneumonia, but the striking feature (which we had not recognised during life) was the co-existence of primary bronchogenic carcinoma.

Clinical impressions without figures to support them are, I know, apt to be misleading; but they can at least point the way towards valuable research. Therefore I feel that this observation, which may or may not be significant, merits an investigation into whether bronchogenic carcinoma is commoner in patients with long-standing chronic bronchitis and emphysema than in the rest of the population.

If this association should be proved, then we should have to revise the teaching that the possibility of bronchogenic carcinoma must be remembered in patients over 40 years of age with *recent* pulmonary symptoms or signs. Instead, whenever chronic bronchitics took "a turn for the worse" we should have to send them to hospital for detailed investigation.

This observation may have an important bearing on the vexed question of tobacco and lung cancer. We know already that all inveterate smokers sooner or later develop a greater or lesser degree of chronic bronchitis. Is it not possible that this chronic bronchitis, per se, renders the smoker especially prone to lung cancer? The analogy of the pneumoconiotic lung being especially prone to tuberculosis springs to mind.

Heathfield, Sussex. **ADRIAN V. ADAMS.**

CONGENITAL ABSENCE OF THE COMMON BILE-DUCT

SIR,—In their interesting report on this subject (Dec. 20), Dr. Durell and Mr. Halliwell point out that only 21 instances of successful operative treatment had been reported up to 1949. It is likely that the successes not reported would increase this number considerably, but nevertheless the condition is rare and operative relief much rarer.

Thus my recent experience, at the Royal Manchester Children's Hospital, of operating on 3 such cases in one week was unusual, and finding 2 of these cases suitable for treatment was even more so. After an anastomosis between Hartmann's pouch and the duodenum, using 'Nylon' sutures, both patients gained coloured stools and lost their jaundice. 1 infant died three weeks later from respiratory distress, present before operation, the cause of which was not found before or after death. The other has done well.

Since there is always a possibility of operative relief all cases with complete congenital bile-duct obstruction should be surgically explored before the liver is too severely damaged.

Manchester. **HERBERT HAXTON.**

TABLET-IDENTIFICATION BOX

SIR,—A tablet-identification box such as that described by Dr. Russell and Dr. Thorne (Dec. 27) can be very easily manufactured out of a large sheet of cardboard and the strips of perforated cardboard which Messrs. Menley & James send out with some of their proprietary preparations. The tablets can be retained in their individual recessed holes with 'Selotape.'

A tablet-identification box on these lines was of great use in a hospital which was constantly admitting patients in coma, whose relatives said they had swallowed some "tablets the doctor gave her," and also children who accidentally swallowed tablets left lying about the house. Accurate knowledge of the tablets swallowed made treatment much easier.

Winchester. **P. G. CRONK.**

HERPES GESTATIONIS AND AUREOMYCIN

SIR,—In your leading article on the Action of Antibiotics[1] you mentioned that certain effects of streptomycin and the newer antibiotics cannot be attributed to their direct action on bacteria and viruses. Thus, for example, the remissions that have been reported in leukæmia, Hodgkin's disease, disseminated lupus erythematosus, and rheumatoid arthritis cannot be direct antibiotic effects. It is also known that these drugs have some action in diseases such as scleroderma, acrodermatitis, and pityriasis rubra, and that this action cannot be explained by their antibiotic properties. In a letter in the same issue Dr. Barnard[2] discussed the same question, and put forward a hypothesis based on the "indirect" action of streptomycin and other "mycins."

We have given aureomycin to a patient with herpes gestationis and, as the result was a partial success, we think this is an example of the "indirect" action of aureomycin.

History and Clinical Findings.—A woman, aged 42, was the mother of five children. The family and personal history showed nothing of note until 1944, when she became pregnant for the sixth time. During the fifth month, irritating skin lesions developed and persisted throughout the pregnancy. She was delivered at term, but the child died immediately afterwards. The skin changes and the irritation then gradually disappeared. In October, 1951, she became pregnant again. After two months, the same skin changes appeared with severe irritation, and on March 25, 1952, she was admitted to hospital.

At this time the skin of the whole body, except the face, was covered with urticarial and papulovesicular lesions, with

potassium, then it was less both in degree and duration, and coalescence with the early sodium retention occurred less often (table III) Typical cases are illustrated in fig 5

Potassium excretion studies were not carried out, save in case 20, this man was in positive potassium balance during every period except the day of operation, when the typical increased potassium excretion took place

CHLORIDE BALANCES

A positive sodium balance was always accompanied by a positive chloride balance of the same order, but the latter was sometimes the greater for no obvious reason Urinary chloride concentrations paralleled those of sodium

EOSINOPHIL-COUNTS AND THE RATIO OF URINARY URIC ACID TO CREATININE

Daily eosinophil-counts were done on 10 patients All showed a pronounced fall to about zero immediately after operation, but the rate of return to normal was very variable and bore no relation to sodium retention Urinary uric-acid creatinine ratios were estimated in the early cases only, they showed similar, but reversed, changes to those of the eosinophils (fig 6)

NITROGEN BALANCE

Nitrogen balances were studied in 6 cases all showed the usual negative balance after operation

Discussion

Many workers have noted the urinary and plasma changes occurring after operation, in association with water and salt retention Continuous balance studies, with a fixed intake before and after operation, enable the whole phenomenon to be more exactly defined and have shown that it results from the fusion of three clearly separable events—namely, primary water retention, early sodium retention, and late sodium retention Depending on the relationship of these last two, the retention of salt and water after operation may be continuous or interrupted

Most of the earlier work dealt with the postoperative retention of saline However, it was clearly shown by Cooper et al (1949) that immediately after there is retention of water, with a urine of h gravity This was also described by Moyer et al and by Ariel (1951) who also recorded the weight-gain None of these workers, howev defined the duration of this retention or th played in the whole Our own results show th water retention is independent of sodium rete is rarely maintained after the first 24 hours, cases 1 and 18 did it last longer The dilutio extracellular fluid resulting from this retention h noted by many observers, in particular by Zi (1951) Stressing that the oliguria occurred at t time as the fall in the eosinophil count, Hard suggested that its origin was adrenocortical T no reason to suppose, however, that these ev causally connected Indeed, the characteristic of primary water retention (oliguria with high gravity and electrolyte concentration) are not th of a release of cortical hormones, but of the anti hormone, and we believe that this is in fact th of this water retention

That antidiuretic hormone is released as the re anæsthesia was suggested by Burnett et al (1949) An Miller (1950) thought that this might occur during ab operations Habif et al (1951) considered that mor pethidine reduced the urine flow by *stimulating* th of this hormone Moyer et al (1949) thought that factors might be responsible for the reduction in urine There is evidence that emotional and other stimuli potentiated by morphine to produce a prolonged re antidiuretic hormone (Lewis et al 1952)

The normal stimulus to a release of this hormone is a in the osmotic pressure of the plasma (Verney and it is possible that this may occur in some cases operating-theatre However, in case 20 care was ta to give intravenous glucose throughout at such a ra to preclude this The release of antidiuretic hor

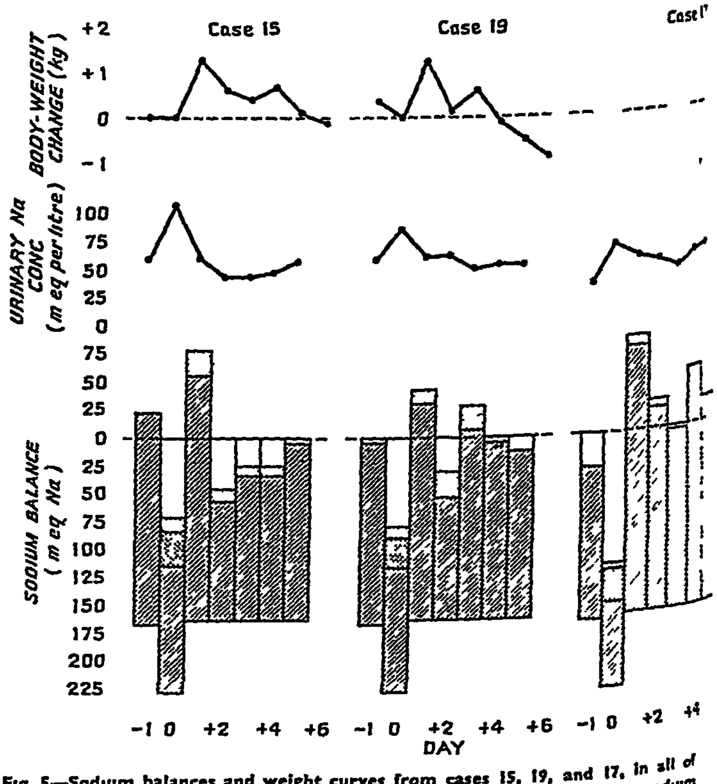

Fig 5—Sodium balances and weight curves from cases 15, 19, and 17, in all of potassium was given In every case primary water retention and early sodium *tion are clearly seen In none of the cases is late sodium retention marke* coalescence is not seen (cf fig 3)

is essential that any substance used in a plasma itute should not interfere with the functioning of normal blood components. In this connection ographic studies have shown that the polyvinyl- lidone used in plasmosan does not form complexes the plasma cations—sodium, potassium, and um—although it forms weak complexes with some valent ions, such as chromium.

full account of these studies, together with their bearing e mechanism of the passage of large molecules through glomeruli, will be published elsewhere. This work was ed out in collaboration with my colleagues, Mr. P. O. e and Mrs. Ingrid G. Ottewill, PH.D.

Obituary

CHARLES HERBERT MELLAND

M.D. Lond., B.Sc. Vict., F.R.C.P.

r. Charles Melland, consulting physician to Man- ster Royal Infirmary, who died on Jan. 8, was ended from a family of long-living doctors practising he Bakewell area of Derbyshire. His father Frederick a practitioner of great repute who, at the age 0, presided at the gathering of old residents of the chester Royal Infirmary assembled to take farewell he old building in Piccadilly.

orn in 1872, Charles was educated at the Manchester mmar School and the medical school at Owens lege. He qualified in 1894 and held a resident and er hospital posts before he was elected physician to oats and the Northern Hospitals. One of his junior pital appointments was that of director of the infant ical laboratory at the infirmary, a very different post n that of the present day. The director cut the sections l carried out the blood-counts, and it was here that lland began to take an interest in diseases of the blood subject in which he later specialised and on which he te several papers. In 1906 he was appointed medical estigator to the Royal Commission on the care and trol of the feeble-minded. His report on the prevalence pilepsy in Manchester was included in the commission's e-book, published in 1908, and this work led to his ointment as honorary physician to the National ociation for the Feeble-minded.

le was appointed to the medical staff at the Man- ster Royal Infirmary in 1914, but the war intervened l he left to serve in the R.A.M.C. On his return he was appointed lecturer in clinical medicine at the versity. In 1921 he was elected F.R.C.P. He retired m the staff of the Infirmary in 1932, but he continued consulting practice.

V. B. writes: "A good walker and an enthusiastic nper who by no means chose pleasant pastures for the ching of his tent, Melland was keenly interested in university lacrosse and mountaineering clubs. The dents showed their appreciation by electing him sident of the athletic union, and he was president of ir lacrosse club when he died, having held the office ively for many years. Until well over 60 he could be n in an old sports coat and grey flannel trousers, king disreputable but supremely happy, keeping goal the B team courageously and in no unskilful manner. Charlie Melland was a physician of the old school; l, gentle, courteous and friendly, giving a sound nion on a difficult case. With the outbreak of the second ld war, he was recalled to duty at the Infirmary and oughout the war years he held a regular outpatient ic and helped in other ways. Those returning from Forces found him much changed; yet, despite the dicaps of ill health and advancing age, he could be nted on to attend, with a progressively lengthening d, the dinners of the Infirmary medical board and suppers of the lacrosse club. He even continued to h the matches of his beloved team and to help with uragement and sound advice. He was watching a ch at the age of 80 on a foggy December afternoon he day his last illness began. Few octogenarians will be mourned and missed so much by the present generation of undergraduates."

Dr. Melland was predeceased by his wife. He leaves a son and a daughter.

BRYAN LESLIE JEAFFRESON

M.D. Lond., F.R.C.S., F.R.C.O.G.

Mr. Bryan Jeaffreson, gynæcological surgeon to the United Leeds Hospitals, died on Jan. 7, after a short illness, at the age of 56.

He stemmed from the Jeaffresons of Framlingham in Suffolk: many of them were well-known surgeons, and the most famous of them is said to have performed the first successful ovariotomy in England, in 1836. From Hurstpierpoint College he went to St. Bartholomew's Hospital; but he spent two years as a private during the first world war, before qualifying in 1921. After serving at St. Bartholomew's as house-surgeon and resident internal midwifery assistant, he went to Sheffield, where he was senior resident officer at the Jessop Hospital, and to Birmingham, where he held a combined registrarship to the gynæcological department and a surgical unit. At this stage of his career he came under the influence of those great teachers, Miles Phillips and Beckwith Whitehouse. Meanwhile he had taken the London M.D. in 1924 and the F.R.C.S. in 1928. In 1929 he was appointed university tutor in obstetrics and gynæcology at Leeds, and after barely a year he became assistant surgeon to the Hospital for Women. There was no vacancy at the Maternity Hospital until 1934, when he became obstetric surgeon there on Dr. McGregor Young's retirement.

He examined for the Universities of Manchester and Sheffield besides his own, and had for many years been presiding examiner at Leeds for the Central Midwives Board. This was a part of his work that he particularly enjoyed, and he carried it out with skill and sympathy. He served on the council of the Royal College of Obstetricians as a member from 1943 to 1949, and in 1950 he was elected to the fellowship. Last year the organisation of the British Congress of Obstetrics and Gynæcology which was held in Leeds fell mainly on him. But the task was congenial, and when the congress was over letters from colleagues from all over the British Isles and from many other parts of the world bore witness to the signal efficiency of his work.

A. M. C. writes: "Though Bryan Jeaffreson had a keen interest in surgical technique, it was perhaps as a teacher that he reached his greatest heights. His ward rounds and outpatient teachings were always crowded. He had a quiet, clear, and dogmatic way of making his points. He was a keen member of the North of England Obstetrical and Gynæcological Society, and we often travelled to meetings together. The last occasion was last month when the council of the society elected him president for 1953, and he appreciated this election as a great honour, though with typical humility he was doubtful of his capacity to do justice to the duties involved; for despite his considerable talents, he was modest to a fault. No man could have wished for a more loyal or dependable colleague."

Mr. Jeaffreson leaves a widow, a son, and a daughter.

WILLIAM JONES RICHARDS

F.R.C.S.

Mr. Richards died on Jan. 1 at Port Talbot, Glam, where he had practised for many years as a surgical consultant on industrial insurance.

He was born in 1873 and he was educated privately and at St. Bartholomew's Hospital. After qualifying in 1897 he spent a few years in the Middlesex county mental service and then turned to surgery, taking the F.R.C.S. in 1906. He held clinical assistantships at St. Luke's Hospital and the Royal London Ophthalmic Hospital, before he settled at Port Talbot. At the outbreak of the 1914–18 war he joined the R.A.M.C. and he served in a field ambulance at Gallipoli and as a surgical specialist in Palestine with the rank of major.

D. R. writes: "Richards had built a reputation for a sound and fair opinion. He was a man of many interests, always ready to help in local activities provided it did not involve any public office. His loss will be felt in many circles and perhaps most in the Church he served so well."

wards Thus, we do not consider the number of children with "sensitivity" manifestations as any accurate indication of the real number of cases Clinical or radiological evidence of the primary infection was present at some time in 80% of the children traced

But we do think that the number of cases of miliary dissemination, bone disease, or meningitis is likely to reflect the risk of these complications in the children infected at the age of less than 5 years Thus in 1020 infected children 16 (1 5%) developed bone lesions (4 of these after treatment for either tuberculous meningitis or miliary tuberculosis) and 42 (4 1%) meningitis or miliary tuberculosis or both, within a minimal period of observation of two years If the possible range is calculated, we find that the risk is 1–2% for bone disease and 2 9–5 5% for either tuberculous meningitis or miliary tuberculosis We would have liked to be able to take our data further and to calculate the risk in children infected before and after the age of 2 years Certainly 31 of the 42 cases of miliary tuberculosis or of tuberculous meningitis occurred in children infected before the age of 2 years, but we did not know if the remaining 11 had been infected before or after their second birthday If we assumed that all the 11 had been infected afterwards, the calculated risks of the development of tuberculous meningitis or miliary were 1 in 20 at the age of less than 2 years and 1 in 30 at the age of more than 2 years, but this difference was not statistically significant

COMMENT

The chances of developing bone lesions, miliary tuberculosis, or tuberculous meningitis are the greatest hazards following the primary infection with tuberculosis It is therefore important that these risks should be measured, and we can only assume that they are not well known because the conditions for their measurement are difficult to obtain

All writers on childhood tuberculosis are agreed that the risk of illness is greatest with infection in the first year of life, remains high until the age of 2 or 3 years, and then diminishes Authors who have followed large series of children infected in the first year or two presenting in hospital clinics or outpatient departments have found a varying mortality, usually about 10–20% of children within five years (Bernard et al 1925, Asserson 1927, Myers and Kernkamp 1930, Wallgren 1938, Brailey 1940) In the Luebeck disaster, which combined heavy oral infection with extremely young age, there was a mortality of 36% (72 from 251) within a year

None of these investigations, however, represents the risk of development of these lesions in all children infected in a given population under natural conditions We have only been able to find one estimate similar in method to ours Holmdahl (1950), in a follow-up designed to study the prognosis in children who had erythema nodosum at the time of primary infection, found that in children aged less than 7 years there was a 2 9% chance of the development of either tuberculous meningitis or miliary tuberculosis within a year of infection, and 3 8% within two years After two years the risk did not increase

It does appear, therefore, that primary infection with tuberculosis in children aged less than 5 years carries a risk of the development of serious complications of about 3–5% This risk is probably not the same for all children aged less than 5 years and is likely to vary with age at infection, and possibly with other factors, such as genetic resistance, with repeated exposures or the development of other infections As yet we have not the data to make any numerical estimate of these factors

SUMMARY

The known rate of conversion in a group of children representative of the childhood population of a city has been used to estimate the number of primary infection in children aged less than 5 years

4% of all children aged less than 5 years were
—1020 from a population of 25,000

We traced 258 of these children and found that within a minimum of two years from infection, 16 (1 5%) had developed lesions of bone and 42 (4 1%) had developed either tuberculous meningitis or miliary tuberculosis, and that 36 (3 5%) had died of tuberculosis

We wish to thank all our friends, and acknowledge the great help we have received in this study, particularly from the chest physicians of the clinics in Newcastle, and the medical staffs of the children's hospitals

INFLUENCE OF CARBOHYDRATE METABOLISM ON BACTERIAL ALLERGY

ITS RELATION TO CORTISONE DESENSITISATION

J. W CORNFORTH M Sc Sydney, D Phil Oxfd
D A LONG M.D Lond

From the National Institute for Medical Research, Mill Hill, London

HYPERSENSITIVITY to streptococcal allergens, ascorbic acid deficiency persisting into convalescence, and endocrine disturbance have all been suspected of playing significant parts in the pathogenesis of rheumatic fever Based on this broad analogy, a study has been made of bacterial allergy (as represented by sensitivity to tuberculin in B C G infected guineapigs), ascorbic acid deficiency, and the effects of various hormones upon them (Long and Miles 1950, Long et al 1951a, b, and c, Cornforth and Long 1952) The limitations of animal experiments in elucidating human pathology have been repeatedly stressed (Long 1951, 1952) Our present views, to which these limitations strictly apply, may be summarised as follows

It has been postulated that, in B C G-infected guinea pigs, cortisone and alloxan facilitate the formation of dehydroascorbic acid (Long et al 1951c), which, by inhibiting phosphoglucomutase, blocks the conversion of glucose-1-phosphate to glucose-6-phosphate—accumulation of glucose 1-phosphate being associated with diminished sensitivity to tuberculin (fig 1) (Cornforth and Long 1952) Organic phosphates representing the various stages of carbohydrate metabolism were therefore tested empirically Among these, adenosine diphosphate (A D P) was shown to have marked desensitising activity, whereas in comparable doses the closely related adenosine triphosphate (A T P) had none (Cornforth and Long 1952)

It is known that the breakdown of glycogen in the tissues (leading in the first stage to glucose 1-phosphate) is sensitive to the equilibrium between A T P and A D P and to the availability of inorganic phosphate This has been emphasised by Potter (1944), who says "It must be recognised that there is a basal rate of A T P breakdown which is balanced by the resting metabolism and that glycogen may be expected to break down only when there is a sudden shift in the A T P/A D P balance" These observations refer to intracellular metabolism but it is possible that such arguments based on intracellular physiology may apply in the tuberculin sensitive

rsity of London

Jan. 7 the following degrees were conferred :

. *Branch I (medicine).*—P. J. Banks, A. F. Barnett, Herbert Barnett Bass, Mary Bateman, S. I. Cohen, Phyllis M. E. Betty B. Dyer, F. R. Ellis, D. G. Evans, D. M. D. Evans, Felix Davies, I. T. Gabe, P. J. D. Heaf, Cherry D. Heath, Jaslowitz, R. P. V. Jayewardene, A. M. Johnson, J. C. d, Wilfrid E. Medd, L. P. A. Newborne, C. P. Newcombe, C. Nordin, M. A. Pears, Betty E. Powe, S. J. G. Semple, Shorter, K. A. Sowden, C. J. Stevenson, Frank Taylor, Thomson, Brenda D. Van Leuven, B. W. Webb.

). *Branch II (pathology).*—Aleck Bernstein, J. L. Brennan, ia C. Brown, L. H. Collier, H. R. Colquitt, J. C. Crook, Phyllis ll, David Marrack, D. J. O'Brien, F. R. Philps, K. A. Porter, ugh, M. V. Salmon, W. J. L. Sladen, C. S. Treip, S. P. B. Way, Williams, A. L. Woolf, E. A. Wright.

D. *Branch III (psychological medicine).*—A. A. Cashmore, Denham, Aleck Folkson, W. P. Gurassa, Julius Merry, *D. J. H. P. Tarnesby, D. L. C. Thomas, G. C. Turle.

D. *Branch IV (midwifery and diseases of women).*—J. C. Samuel Burke, Frank Denny, James Elstub, G. W. Garland, S. Gordon, J. M. Holmes, Rustam Moolan-Feroze, Elsie M. orpe, N. G. G. Talbot.

D. *Branch V (hygiene).*—J. D. B. Andrews, J. R. Mayers, J. Thomas.

D. *Branch VI (tropical medicine).*—J. C. L. Adams, P. B. ison, A. C. S. Hobson.

* Mark of distinction, university medal.

ersity of Bristol

e dissertations of A. O. Chick and E. J. Field for the e of PH.D. in the faculty of medicine have been approved.

ersity of St. Andrews

Heneage Ogilvie, consulting surgeon to Guy's Hospital, lon, has been appointed praelector in the faculty of cine for 1952–53. During his tenure of office he will take in the teaching and clinical work of the department of ry and deliver a series of open lectures.

al College of Surgeons of England

a meeting of the council held on Jan. 8, with Sir Cecil eley, the president, in the chair, the Cecil Joll prize for was awarded to Mr. Geoffrey Keynes. A Laming Evans arch fellowship was awarded to Dr. Angus McPherson for research into the blood-flow changes in the limbs in omyelitis. A Hunterian professorship was awarded to H. R. Dew for a lecture to be delivered during his visit Sir Arthur Sims Commonwealth travelling professor in 3. Erasmus Wilson demonstratorships were awarded to V. E. Negus, Sir Frank Colyer, and Dr. B. E. Heard, and Arnott demonstratorship to Mr. L. E. C. Norbury.

he following were elected to the fellowship of the Faculty næsthetists :

r. J. G. Bourne (Salisbury), Dr. H. G. Epstein (Oxford), Prof. nando Hudon (Quebec), Dr. J. V. Mitchell (Oxford), Dr. G. xson-Rees (Liverpool), Dr. Arnold Robertson (Brisbane), Dr. A. er (New Zealand), Dr. B. N. Sircar (Bombay).

iplomas of membership were granted to A. G. N. Calder, G. Lupprian, and N. E. Pitts. Diplomas were also awarded, tly with the Royal College of Physicians, to the following :

.C.H.—Anima Banerjee.

.A.—D. E. Argent, Anima Banerjee, D. W. Barron, M. McC. rows, K. B. Chambers, C. C. D. Chandler, H. S. Cohen, E. A. per, J. S. Crawford, D. W. J. Cullingford, L. D. Davidson, H. Egerton, Sam Galloon, Rosalinde J. Harrison, Pamela M. lings, Frances S. Huxley, E. G. A. Jackson, J. W. Latham, A. L. Leatherdale, Samuel McKechnie, A. V. McVey, A. H. B. ison, R. A. Millar, A. C. Milne, P. R. H. Molesworth, Ruth phy, E. J. O'Mullane, Doreen B. Pallot, James Parkhouse, il Pearce, D. J. Pearce, Subramaniam Ponnambalam, L. T. Rees, V. H. Robinson, F. M. Sandford, P. H. Simmons, W. D. Turner, . White.

.P.M.—R. H. Boardman, Kunhunni Nayar Kothaneth, T. R. loy, T. L. Pilkington, J. W. Warboys.

.T.M. & H.—Hashim Barakat, Mohindra Singh Boparai, Tahir za.

.P.—J. N. Dearnaley, J. S. Elwood, M. M. Friedman, E. M. k, Jean E. D. Taylor.

yal Faculty of Physicians and Surgeons of Glasgow

At a meeting of the faculty on Jan. 5, with Dr. Andrew ison, the president, in the chair, Oon Teik Khoo and endra Chandra Mallik were admitted fellows of faculty physician.

ffield Dental Fellowships

One of the aims of these fellowships is to enable graduates medicine and science to undertake teaching and funda- ntal research on dental health and disease. The annual ue of a fellowship is between £500 and £800 a year. Further ticulars will be found in our advertisement columns.

Medical Research Council

The council invite applications for the following fellowships for 1953–54 :

Rockefeller Travelling Fellowships.—These fellowships are intended for graduates resident in this country who have had some training in research work in clinical medicine or surgery, or in some other branch of medical science, and who are likely to profit by a period of work at a centre in the United States or elsewhere abroad, before taking up positions for higher teaching or research in the United Kingdom. Fellowships tenable in the United States will normally carry a maintenance allowance at the rate of $2600 per annum for a single fellow and $3600 per annum for a married fellow. Provision will also be made for travelling and other approved expenses. Applications should reach the secretary of the council not later than March 15.

Eli Lilly Fellowships.—These fellowships, tenable in the United States, are offered on terms and conditions similar to those attaching to the Rockefeller fellowships.

Dorothy Temple Cross Research Fellowships in Tuberculosis.—These fellowships offer opportunities for study or research to British doctors who intend "to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis." The fellowships will, as a rule, be awarded to candidates who wish to make their studies or inquiries elsewhere than in the United Kingdom. They provide for the payment of a maintenance allowance at the rate of £650 per annum for a single fellow and £900 per annum for a married fellow. An allowance will also be made for travelling and other approved expenses. Applications by March 15.

Alexander Pigott Wernher Travelling Fellowships in Ophthalmology and Otology.—These fellowships are intended for medical graduates who are likely to profit by a period of work in ophthalmology or otology at a centre abroad before taking up positions for higher teaching and research in these branches of medical science. They are normally tenable for one year. A maintenance allowance at the rate of £650 per annum is offered for a single fellow or £900 per annum for a married fellow ; in addition, an allowance is made for travelling and other approved expenses. Applications by March 31.

Further information about all these fellowships may be had from the secretary of the council, 38, Old Queen Street, London, S.W.1.

Food and the Future

The second meeting in the series on this subject which is being held by the food group and nutrition panel of the Society of Chemical Industry will be held on Wednesday, Jan. 28, at 6.15 P.M., at the Chemical Society's rooms, Burlington House, Piccadilly, London, W.1, when Dr. G. A. C. Herklots and Prof. John Yudkin will discuss Present Methods of Attack on the Problem.

Positive Health Measure in Industry

The Industrial Welfare Society are holding four weekly lectures on this subject on Thursdays at 6 P.M., at their rooms at 48, Bryanston Square, London, W.1. Dr. Neil Marr will speak on Organisation of First Aid in Work Places (Jan. 22), Dr. P. Fitzsimons on Sickness Absenteeism (Jan. 29), Mr. W. F. Floyd, PH.D., on Posture and Movement in Relation to Industrial Health (Feb. 5), and Dr. F. M. Oldershaw on Health Education in Industry (Feb. 12). Further particulars may be had from the administrative officer of the society.

Nuffield Lodge

The Nuffield Foundation and the Nuffield Provincial Hospitals Trust are moving from 12 and 13, Mecklenburgh Square, London, W.C.1, on Jan. 22, 1953, to Nuffield Lodge, Regent's Park, London, N.W.1 (Primrose 8871–5). The National Corporation for the Care of Old People will also be moving to the same address from 33, Doughty Street, W.C.1. The address of the trust's Investigation into the Functions and Design of Hospitals will be 33, Doughty Street, W.C.1 (Terminus 5288) from Jan. 22 until further notice. Nuffield Lodge is the new name given, with the consent of the Commissioners of Crown Lands, to Grove House (opposite St. John's Wood Church), which the foundation has acquired for the future headquarters of itself and associated trusts.

Anglo-French Exchange Bursaries

Applications are invited for bursaries which will be awarded this year to young British doctors under the exchange scheme arranged by the French Embassy in London between the Institut National d'Hygiène in Paris and the Ciba Foundation in London.

The value of the French grants is 60,000 francs a month tax-free, and they will be awarded for periods of two to four months to doctors who wish to obtain clinical experience or carry out medical research in France. The following are members of the British selection board : Prof. Alexander Haddow, Prof. John McMichael ; *representatives* of the British Council (Dr. Margaret Suttill), the British Postgraduate Medical Federation (Dr. C. F. Hamilton-Turner), and the Medical Research Council (Dr. F. J. C. Herrald) ; joint secretaries, Miss A. M. Vidal-Hall (French Embassy) and Dr. G. E. W. Wolstenholme (Ciba Foundation). Applications should be sent before March 31 to Dr. Wolstenholme, 41, Portland Place, London, W.1.

As in previous work, the diameter of the tuberculin lesions after twenty-four hours was found to be proportional to the logarithm of the dose of tuberculin, and it was possible to estimate the degree of sensitivity by the relative positions of the dosage-response lines fitted to the mean lesion-diameters plotted against the logarithm of the dose Changes in sensitivity are measured in terms of the change in potency of standard doses of tuberculin compared with that in control animals Thus a potency ratio of 0 25 indicates a fourfold decrease, of 4 00 a fourfold increase in sensitivity The probability that ratios differing from unity indicate a significant change in sensitivity is expressed by the value of P in the tables Ratios for which P is 0 05 or less are considered significant

TABLE I—ANALYSIS OF RESULTS OF EXPERIMENTS

Expt	Agent and dose per kg body-weight	Variance ratio*	P	Potency ratio
1	ATP (10 mg) + ADP (2 mg)	< 1	—	0 925
	ATP (2 mg) + ADP (2 mg)	27 59	< 0 001	0 464
	ATP (1 mg) + ADP (2 mg)	56 54	< 0 001	0 252
2	ATP (10 mg)	< 1	—	1 09
	Alloxan (50 mg)	75 05	< 0 001	0 423
	Alloxan (50 mg) + ATP (10 mg)	< 1	—	0 912
	Cortisone acetate (5 mg)	79 81	< 0 001	0 462
	Cortisone (5 mg) + ATP (10 mg)	17 81	< 0 001	1 434
	Dehydroascorbic acid (50 mg)	60 04	< 0 001	0 519
	Dehydroascorbic acid (50 mg) + ATP (10 mg)	—	—	1 000
	Glucose 1 phosphate (0 01 mg)	162 42	< 0 001	0 325
	Glucose 1 phosphate (0 01 mg) + ATP (10 mg)	182 46	< 0 001	0 312
3	Insulin (2 units) injected 0 hours before tuberculin	2 14	>0 10	1 23
	Injected 2 hours before tuberculin	7 42	< 0 05	0 596
	Injected 4 hours before tuberculin	18 99	< 0 001	0 500
	Injected 6 hours before tuberculin	49 18	< 0 001	0 458
	Insulin (2 units) in ascorbic acid deficient guineapigs injected 6 hours before tuberculin	5 03	> 0 05	1 445
	Insulin (2 units) injected 6 + mg) d 6	1 26	> 0 20	1 18
	hours before tuberculin + *ATP (10 mg)*	43 07	< 0 001	2 06
4	Alloxan (50 mg)	51 28	< 0 001	0 466
	Alloxan (50 mg) + insulin (2 units)	< 1	—	1 182
	Cortisone acetate (5 mg)	92 03	< 0 001	0 295
	Cortisone + insulin (2 units)	9 38	< 0 05	1 953
	Dehydroascorbic acid (50 mg)	84 97	< 0 001	0 249
	Dehydroascorbic acid (50 mg) + insulin (2 units)	< 1	—	1 034
	Glucose 1 phosphate (0 01 mg)	53 02	< 0 001	0 366
	Glucose 1 phosphate (0 01 mg) + insulin (2 units)	61 38	< 0 001	0 364
5	Growth hormone (10 mg per kg) injected 0 hours before tuberculin	3 47	> 0 05	0 733
	Injected 3 hours before tuberculin	129 07	< 0 001	0 14
	Injected 9 hours before tuberculin	214 07	< 0 001	0 08
	Injected 12 hours before tuberculin	559 11	< 0 001	0 04
	Growth hormone (10 mg) at 0 hours + cortisone acetate (5 mg)	270 17	< 0 001	0 084†
	Cortisone acetate (5 mg)	25 24	< 0 001	0 545
6	Growth hormone (10 mg) injected 6 hours before tuberculin	163 35	< 0 001	0 279
	Growth hormone (10 mg) + ATP (5 mg)	111 09	< 0 001	0 346
	mg) + *(150 mg)*	*171 94*	*< 0 001*	*0 287*
	mg) +	81 52	< 0 001	0 332
	Growth hormone (10 mg) in ascorbic acid deficient animals	51 82	< 0 001	0 253

* Ratios of "between treatments" variance to error variance

† Cortisone acetate + growth hormone produced effects significantly greater than either alone
Alloxan + growth hormone also produced an effect significantly greater than either alone
These synergistic effects did not occur in ascorbic acid deficient guineapigs

TABLE II—CONDITIONS IN WHICH DESENSITISATION
WITH THE AGENTS TESTED

Agent and dose per kg body weight	Normal diet	Ascorbic acid deficient diet	Reduced glutathione (150 mg per kg)	ATP (10 mg per kg)	[illegible]
Alloxan (25–50 mg)	+	–	–	–	–
Cortisone acetate (5 mg)	+	–	–	–*	–
Dehydroascorbic acid (50 mg)	+	+	–	–	–
Glucose 1 phosphate (0 01 mg)	+	+	+	+	–
Growth hormone (10 mg)	+	+	+	+	–
Insulin (2 units) (compensatory phase succeeding hypoglycæmia)	+	–	–	–*	

+ = desensitisation – = no desensitisation
* Sensitivity significantly *greater* than in controls

RESULTS

Adenosine Triphosphate

The ATP used in these experiments contained a small proportion of ADP which was taken into account when calculating the amounts of the two substances

The simultaneous injection of ATP (1 mg per kg body-weight) and ADP (2 mg per kg) caused a significant fourfold diminution in sensitivity, the effect was halved when the dose of ATP was doubled and abolished by a tenfold increase (experiment 1 table I) Thus, by increasing the ratio of ATP to ADP, desensitisation was prevented

The injection of ATP (10 mg per kg) did not in itself influence sensitivity, but in cortisone treated animals (5 mg per kg), it not only abolished but significantly increased sensitivity to tuberculin, however, it merely abolished the desensitising action of alloxan (50 mg per kg) and dehydroascorbic acid (50 mg per kg), and it did not influence that of glucose-1-phosphate (0 01 mg per kg) (experiment 2). These results, excluding the marked hypersensitivity in animals treated with both cortisone and ATP, had, as already stated, been expected The explanation of these effects may perhaps be inferred by considering the mechanism by which ATP may inhibit glycogen breakdown Stimulation of the hexokinase reaction by ATP leads to the disappearance of inorganic phosphate fixed during the later oxidative stages of glucolysis Cori and Cori (1940) showed that, when the ratio of inorganic phosphate to glucose-1-phosphate falls below a certain level, glycogen splitting (i e, production of glucose-1-phosphate) ceases and glycogen synthesis occurs The reason for the special effect of cortisone may be that (unlike alloxan or dehydroascorbic acid) it induces *synthesis of glucose from protein* Fuel is the provided for the hexokinase reaction and more inorganic phosphate disappears Some of the glucose mobilised by cortisone is known to be converted through glucose-1 phosphate to glycogen, but in the special circumstance under discussion this should not cause accumulation of glucose 1 phosphate, the concentration of which would remain low so long as there was a shortage of inorganic phosphate

Insulin

Insulin (2 units per kg body-weight) injected at the same time as the tuberculin (0 hours) did not significantly influence sensitivity, but injected four or six hour beforehand, it markedly depressed sensitivity (experiment 3) This experiment was repeated and tuberculin sensitivity was *plotted* against blood-sugar levels (fig 3) as hyperglycæmia succeeded hypoglycæmia, sensitivity

TOPERATIVE WATER AND SODIUM RETENTION

P. Le Quesne
A. Oxfd, F.R.C.S.

A. A. G. Lewis
B.Sc., M.D. Lond., M.R.C.P.

the Department of Surgical Studies and the Professorial Medical Unit, Middlesex Hospital, London

many years it has been known that after surgical tions there are changes in the metabolism of water alt. Pringle et al. (1905) first observed the oliguria ing operation. In more recent times interest in the ct was stimulated by the work of Coller et al. (1936) of Avery Jones and Naunton Morgan (1938), and that time numerous studies have been made. ever, from the accumulated evidence no clear picture e nature and magnitude of these changes could be n. We therefore planned to investigate this problem the simplest methods, and maintaining as far as ble a fixed intake of water and electrolytes before, ig, and after operation. This intake was designed as the ideal one for routine use, but to demonstrate uivocally any depression of excretion which might r postoperatively.

MATERIAL

ses of gastrectomy in men form the basis of this , as their study involved the least departure from al routine.

group of 21 routine admissions to a general surgical was studied. Of the 21 patients, 19 underwent otal gastrectomy for benign peptic ulceration, 1 sion of the sigmoid colon for carcinoma, and 1 inguinal iorrhaphy. All the patients were well-nourished ; their average age was 50·5 years, the range being 4 years.

ll the patients were operated on under general sthesia, a wide variety of agents being used. All ived a preoperative injection of either morphine or idine (with atropine or scopolamine), and postatively all received either of these drugs as required. lifference in our results could be detected from these ing combinations.

Methods

alance studies were made from 8 A.M. to 8 A.M. for days before operation and 1–8 days afterwards ; ughout this article the word "day" implies such a nce period. The day of operation is termed day 0. he operation began at 9 A.M. in all but 2 cases, the perative medication was given at the start of a od.

ring the preoperative days the patients were fed solely he following mixture, given by slow drip down a Ryle's for 16 hours out of the 24 :

Casinal	80 g.
Glucose	250 g.
Arachis oil (emulsified with acacia) ..	150 ml.
Ascorbic acid	100 mg.
Water to	3000 ml.

This mixture provided 2600 calories and 70 g. of protein, but no sodium or potassium salts, which were added in a known amount as required. The patients were also given a litre of water to drink in the 24 hours, making the total intake 4 litres per day.

On the day of operation and until they could be allowed to take 4 litres of fluid a day by mouth, the patients were given continuous intravenous fluids—5% glucose, normal saline, and in certain cases (group 3 below) 0·375% potassium chloride or a mixture of potassium phosphates. Oral fluids gradually replaced intravenous in the usual way, the preoperative feeding being resumed by the 4th or 5th day ; during this transition it was impossible to maintain a fixed water intake, but this was never allowed to fall below 4 litres in 24 hours. Apart from the blood given at operation the daily electrolyte intake was accurately maintained as follows :

Group 1.—In cases 1–8 160–170 m.eq. of sodium chloride (about 10 g.) was given throughout. In 1 other (case 9) this level was halved.

Group 2.—In cases 10–13 no sodium was given from the day of operation onwards.

Group 3.—Cases 14–20 received 160–170 m.eq. (about 10 g.) of sodium chloride and 100 m.eq. of potassium. On the day of operation this potassium intake was halved because of the reduced urine volume.

1 patient (case 21) undergoing herniorrhaphy was fed by mouth throughout, the diet containing approximately 85 m.eq. of sodium chloride (5 g.) per day. All patients (cases 1–20), save this last one, also received 500 ml. citrated blood during the operation, giving them an extra 60 m.eq. of sodium, 5 m.eq. of potassium, and 35 m.eq. of chloride in that period.

The volume, specific gravity, and sodium and chloride concentrations of pooled 24-hour urine specimens were estimated, and in some cases the nitrogen, uric acid, and creatinine. The sodium, chloride, and nitrogen content of pooled specimens of gastric juice, removed by routine aspiration, were also estimated. In some cases, during the first 2 hours of each period, 10 ml. of venous blood was drawn into a heparin tube for the following estimations : plasma-proteins, by the method of Phillips et al. (1950) ; plasma-chloride, by the Volhard-Harvey method ; plasma-sodium, by the method of Albanese and Lein (1948) as modified by Chalmers et al. (1951) ; and eosinophils (Randolph 1949).

The following methods were used for urinary determinations : nitrogen, micro-Kjeldahl digestion and nesslerisation ; creatinine and uric acid, King's (1951) modifications of Folin's method and of Benedict and Franke's method respectively. A flame-photometer was used for some of the later estimations of sodium and potassium.

These patients passed almost no fæces on this régime. On the 3rd morning postoperatively a small glycerin enema was

hormone and of cortisone are brought about by different and synergistic mechanisms *Their site of action is therefore likely to be different* We suggest that, in contrast to the action of cortisone, growth hormone blocks hexokinase activity, and that under its influence the body relies for its energy to a greater extent upon glycogen breakdown, *associated with glucose-1-phosphate formation* This would explain the synergistic effect of growth hormone with both cortisone and alloxan, since blocking phosphoglucomutase in an animal which is breaking down glycogen will cause an accumulation of glucose 1-phosphate and also oppose A T P formation

SUMMARY

Using the response to intradermal tuberculin as a measure of allergic hypersensitivity in albino guineapigs *injected with* B C G, *we find that*

(1) Single subcutaneous injections of adenosine diphosphate diminish sensitivity This desensitising action is first diminished and then abolished by the simultaneous injection of increasing amounts of adenosine triphosphate

(2) Single subcutaneous injections of adenosine triphosphate prevent desensitisation by alloxan, cortisone acetate, and dehydroascorbic acid They do not influence desensitisation by glucose-1-phosphate

(3) Single subcutaneous injections of adenosine triphosphate not only abolish desensitisation by cortisone acetate but actually increase hypersensitivity

(4) Single subcutaneous injections of insulin do not in themselves significantly influence sensitivity The compensatory phase that succeeds insulin hypoglycæmia is associated with desensitisation

(5) The *desensitisation that succeeds insulin* hypoglycæmia is thought to be due to naturally liberated cortisone, since it does not occur in ascorbic-acid-deficient animals, is prevented by injection of reduced glutathione, and is intensified by injection of adenosine triphosphate

(6) Single subcutaneous injections of insulin prevent desensitisation by alloxan and dehydroascorbic acid, they not only prevent desensitisation but intensify sensitivity in animals treated with cortisone acetate, and they are without effect on the desensitising action of glucose-1-phosphate

(7) Single subcutaneous injections of growth hormone depress sensitivity to tuberculin This action was unaffected under our experimental conditions by injection of reduced glutathione, A T P, or insulin, or by ascorbic-acid deficiency

(8) In desensitisation, growth hormone (given in single subcutaneous injections) has a synergistic action with either cortisone acetate or alloxan

Our present hypothesis (see fig 2) provides a convenient summary of these facts We have previously suggested that cortisone facilitates the oxidation of ascorbic acid to dehydroascorbic acid, which inactivates phosphoglucomutase, and thus blocks glycogen breakdown and increases the tissue concentration of glucose 1-phosphate—which is intimately concerned with desensitisation We now suggest that adenosine triphosphate and insulin *oppose* this desensitisation by stimulating hexokinase activity, leading to a disappearance of inorganic phosphate which would otherwise be used for glucose 1-phosphate formation from glycogen This effect is actually enhanced by the glucose formed from protein under the influence of cortisone, more glucose being thus provided for the hexokinase reaction

The desensitisation produced by adenosine diphosphate and by growth hormone is ascribed to the effect of these substances in *causing breakdown of glycogen to* glucose-1-phosphate, with the hormone, at least, this effect is considered to be due to inhibition of hexokinase activity

We are indebted to Dr Knud Tolderlund of the State Serum Institute, Copenhagen, for the B C G, to Messrs Armour, of Chicago and London, for a generous gift of growth hormone, to Dr A Morrison, of Roche Products Ltd, Hertfordshire, for alloxan, dehydroascorbic acid, and red glutathione, *to our colleague Dr R Porter for the m and to Prof F G Young,* F R S, *for some highly p* growth hormone

We are greatly indebted to Miss M V Mussett for stat analyses not only on the experiments described here also on a large number of unquoted confirmatory experim *on which these observations are based*

THE PREVENTION OF POSTOPERATIVE PULMONARY ATELECTASIS *

K N V PALMER
M D Camb, M R C P
CLINICAL RESEARCH ASSISTANT

B A SELLICK
M B Lond, D A
CONSULTANT ANÆSTHETIST

MIDDLESEX HOSPITAL, LONDON

IN the forty years since postoperative pulmonary atelectasis was recognised by William Pasteur at the Middlesex Hospital (Pasteur 1908, 1910) there has been *little change in the incidence of this complication* despite advances made in surgery and anæsthesia and the introduction of antibiotics

The prevention and treatment of this condition is important because atelectatic areas readily become infected, leading to bronchopneumonia (Coryllos 1929, 1930)

Segmental atelectasis is the common postoperative pulmonary abnormality and it was found in 94% of patients who developed pulmonary complications after abdominal operations (Palmer 1952) It results from occlusion of the smaller bronchi by retained secretion and the absorption of air distal to the block (Coryllos 1929, 1930) The lesion is commonly basal and unilateral, but it may be bilateral and involve segments of the middle lobe or lingula (Palmer and Sellick 1952b)

We describe here a method for the *prevention* of postoperative atelectasis It is based on the hypothesis that, if the factors which favour the retention of sputum in patients after operation can be overcome, atelectasis should seldom occur

ÆTIOLOGY

Table I shows that the many factors concerned in the production of atelectasis ultimately have their effect by causing retention of sputum We consider that a deficient expulsive mechanism, a reduction in bronchial calibre, and qualitative or quantitative changes in the bronchial secretion are all of great importance

The cough reflex is the mechanism by which excess secretion is normally removed from the large bronchi (Ballon 1939, Bullowa 1944) After *abdominal* operations coughing is restricted owing to pain from the wound and the cough is rendered weak and ineffective by the semirecumbent posture, impaired diaphragmatic gravity and sodium concentration (fig. 3), these being reversed on the second day. A high sodium concentration therefore coincides with a ium excretion on the day of operation, while rinary sodium concentration may occur with a retion on the next day.

---

* Part of this work was included in a thesis for the degree of M D Camb by one of us (K N V P)

lium Retention

ell as this early retention, there was a later, more ed, period of sodium retention characterised by sodium balance, low urine sodium concentration, ter retention with corresponding weight changes. egan on 0+1 or 0+2, and therefore might ier separated from the early sodium retention king the excretion on 0+1, might coalesce with rly phase. It might be maximal on any of t few postoperative days, and its duration was e. These variations are illustrated by cases 7, 5, (fig. 3). *It will be seen that in cases 5 and 1 there* ntinuous postoperative salt and water retention, to the coalescence of three separate events.

t this later retention is primarily one of sodium and water is shown by fig. 4, illustrating the data from 3, in which the patient received no sodium for 4 fter operation. Here the weight fell steadily as the of the low calorie intake, despite the fact that as water was given as in the other cases.

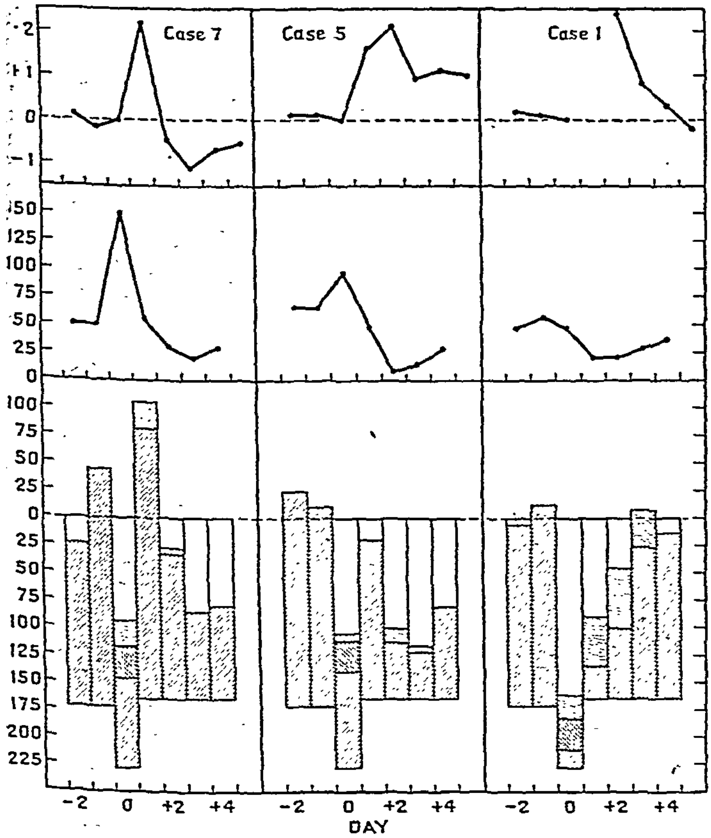
INFLUENCE OF POTASSIUM INTAKE

The effect of giving potassium can be seen by comparing the results in cases 14–20, where this ion was given as described, with those in cases 1–9 where none was given.

Reference to table I shows that "primary water retention" occurred in both groups, though it was slightly less in the group receiving potassium. Applying *the "t" test of significance of the difference* between the means of small samples (Fisher 1946), $n = 10$; $t = 2{\cdot}873$; $P < 0{\cdot}05$, suggesting that the difference between the two groups is significant.

Potassium deficiency has been shown to cause sodium retention (Black and Milne 1952), but our observations on other cases (to be published later) show that the time of this retention is variable. Presumably this was the cause of the preoperative sodium retention in cases 3 and 4, but postoperative retention occurred whether or not potassium was given. "Early sodium retention" occurred in both groups, the average being 95 m.eq. in the group receiving potassium as against 122 m.eq. in the other. Applying the same test as above, $n = 12$; $t = 1{\cdot}74$; $P > 0{\cdot}05$. Even if no allowance were made for loss of sodium on the operating-table, P is still greater than 0·05.

"Late sodium retention" was the only one of the three phases which was greatly modified by giving



—Sodium balances and weight-changes in cases 7, 5, and 1: in all three cases the ght is adjusted to zero on the morning of operation. In case 7 early and late sodium ntion are clearly separated, in case 5 they are distinct, whereas in case 1 they e coalesced.

ary water retention and that secondary to late sodium retention are lected in the weight-changes. In a 5-day period on an intake of only 100 g. icose the normal subject loses nearly 200 m.eq. sodium (Gamble 1951). e urinary sodium excretions on the day of operation and the day after it the reverse of what might be expected from the urinary concentrations, ing to primary water retention followed by water excretion.

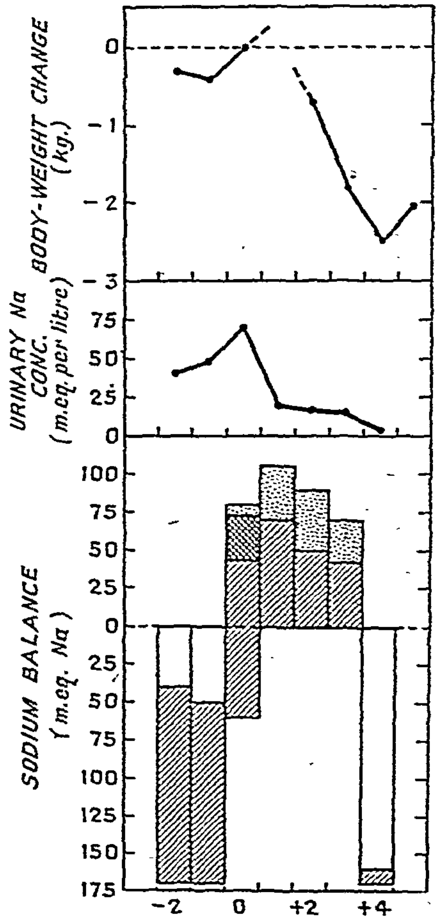


Fig. 4—Full data in case 13, in which no sodium was given after operation apart from that in a blood-transfusion. Although the water intake was maintained throughout at 4 litres per day the weight fell steadily, showing that water is not retained after the first 24 hours in the absence of sodium retention (cf. fig. 1).

tion in patients who develop atelectasis (Palmer and Sellick 1952b)

Preoperative Treatment

(1) Oral inhalation of 1 ml of 1% solution, of isoprenaline ('Neo-Epinine Solution No 1,' Burroughs Wellcome & Co) by means of a hand inhaler three times a day

(2) This is followed by fifteen to twenty minutes' postural drainage The foot of the bed is raised at least 18 in with blocks or a metal stand The treatment consists in clapping and vibration percussion to the chest wall, especially the basal regions, in the expiratory phase of respiration This is done with the patient in the two lateral positions (side-lying) and prone Five to ten minutes' treatment is given in each position This treatment should be continued thrice daily until no sputum is produced when the patient is tipped

Although patients may not confess to a productive cough, sputum is usually produced when they are tipped Many patients with chronic bronchitis have been seen who produced two or three ounces of mucoid or mucopurulent sputum when tipped for the first time After a week's treatment, no sputum was produced, the rhonchi disappeared, and the breathing was much easier Severe cases of bronchitis may require fourteen days' preparation before the operation

All cases should have 1 ml of isoprenaline by inhalation and be tipped immediately before the preoperative injection Very occasionally patients react to the isoprenaline with tachycardia, pallor, and restlessness The first dose, therefore, should be given slowly If there is a reaction, 0 25 ml can usually be given without any side-effect In emergency abdominal surgery postural drainage may be contra-indicated, but the patient should be given a full dose of isoprenaline by inhalation

Postoperative Treatment

(1) As soon as consciousness is regained, the patient should be given an inhalation of 1 ml of 1% isoprenaline, and this is repeated six-hourly

(2) When his general condition permits (usually from six to twelve hours after operation) postural drainage is given six-hourly If the prone position is not tolerated, the treatment should be given in both lateral positions

Treatment is continued as long as sputum is produced on tipping All patients should have at least five days' treatment, and it is essential that during the first twenty-four hours the treatment should be thorough If there is clinical or radiological evidence of atelectasis, it should be given hourly If the affected portion of the lung has not expanded clinically within twelve hours (shown by the return of normal breath sounds) bronchoscopy should be considered

This regimen proved very satisfactory in a small number of high-risk cases in which the patients were not considered fit for operation because of the condition of the chest It was therefore decided to test its efficiency in a controlled series of cases

INVESTIGATIONS

An unselected consecutive series of 180 patients admitted for repair of inguinal hernia or for partial gastrectomy for peptic ulcer were divided into two groups with the help of tables of random numbers (Fisher and Yates 1938) These groups were treated as follows

Group E postural drainage and the inhalation of isoprenaline before and after operation (as described above)

Group O breathing exercises before and after operation

All the patients were given procaine penicillin 600,000 units b d before and after operation as a routine

The sex-incidence and age incidence and the number of smokers, bronchitics, and hernia cases were satisfactorily distributed in the groups (table II) Each patient was examined clinically before operation and thereafter daily The clinical diagnosis of atelectasis is difficult during the first twenty-four hours after operation, when it is most likely to develop (Stringer 1947, Palmer 1952) We have, therefore, relied on ra logical findings X-ray films of the chest were tak before operation and, with a portable apparatu, af the operation Minimal changes, such as promin of the basal markings and slight elevation of the d phragm, which have been reported as normal ra logical findings after abdominal operations (Muller et al 1929), were not considered to constitute any abnormal Only unequivocal radiological evidence of atelecta was accepted, and the films were reported on by t same radiologist, who did not know to which treatm group the patient belonged

TABLE II—COMPARISON OF TWO GROUPS OF UNSELEC PATIENTS

Group	No of patients	No with history of bronchitis	No of smokers	No of females	No of hernia cases	[illegible]
E	90	44	67	19	22	[illegible]
O	90	39	59	13	24	[illegible]
		$\chi^2 = 0\ 56$ n = 1 P > 0 50 Not significant	$\chi^2 = 1\ 69$ n = 1 P > 0 10 Not significant	$\chi^2 = 1\ 46$ n = 1 P > 0 20 Not significant	$\chi = 1\ 17$ n = 1 P > 0 20 Not significant	

Of the group E patients 8 (9%) showed radiolog evidence (table III) of atelectasis, compared with (43%) of group O None of the patients in group E had a productive cough lasting a week or more af operation, whereas this was present in 30 (33%) of group O

This regimen is clearly effective in preventing po operative atelectasis It is successful because it enab the patient to remove secretion from the lungs afte the operation In high-risk cases the amount of sputu is reduced by preoperative treatment

Aronovitch (1945) and Scurr (1951), using a broncho-dilator alone, reported good results in the preventi of atelectasis If atelectasis could be prevented by using isoprenaline alone, the treatment would b simplified An experiment was therefore undertake to determine whether postural drainage with vibrat and clapping percussion alone or isoprenaline by inhalation alone was effective in preventing atelecta

160 consecutive unselected patients undergoing an operation for the repair of inguinal hernia or for partial gastrectomy for chronic peptic ulcer were divided into four groups with the help of tables of random numbers (Fisher and Yates 1938) These groups were treate as follows

Group 1 isoprenaline by inhalation alone before and afte operation

Group 2 isoprenaline and postural drainage and vibrator percussion as described above

Group 3 postural drainage with vibratory and clapp percussion alone before and after operation

Group 4 breathing exercises before and after operatio All the patients were given procaine penicillin and were examined clinically and radiologically before and after operation as in the previous experiment

Table IV shows that there was a satisfacto [illegible] tion of high-risk cases in the groups Much ex

5—Eosinophil-count and urinary uric-acid/creatinine ratio in 2 es undergoing gastrectomy. The characteristic fall of eosinophils the day of operation is shown; but the return to normal was st variable, and bore no apparent relation to the extent or duration sodium retention. The uric-acid/creatinine ratio showed reversed : similar changes.

no less prolonged than in other cases, thus showing : hypertonicity is not the essential factor. Morphine, sthesia, trauma, and emotion are probably the ortant stimuli.

he postoperative retention of salt has often been estigated. In 1944 Coller et al. clearly stressed the ger of giving too much salt in this period, and reported ses made œdematous in this way. Wilkinson et al. 49) related the sodium retention to the postoperative ogen loss, and suggested that both were parts of a plex reaction to trauma—an aspect which has been lied in great detail by Moore and Ball (1952). Search published work has not disclosed any description of separable episodes of sodium retention, though some lished balance studies, particularly those of Howard Mason (1946), show both to have occurred. Indeed, s possible to distinguish in their studies examples of three patterns of sodium retention that we have cribed (separated, distinct, and coalescent retention). he evidence that postoperative sodium retention is ely adrenocortical in origin is considerable (Moore Ball 1952). In particular, the increased excretion of assium and nitrogen, the fall in circulating eosinophils, rise in the uric-acid/creatinine ratio, and the increased nary excretion of glycogenic corticoids are all conent with this hypothesis. Since our results show that ium retention often occurs in two phases, some dification of this hypothesis appears necessary.

t is possible that the hypotonicity resulting from ter retention during the early part of the day of ration stimulates sodium retention later in this iod, and so causes the early sodium retention. But lland and Stead (1951) have shown that hypotonicity uced after pitressin injection does not cause sodium ention. Hæmodynamic factors may be largely responle for early sodium retention. Coller et al. (1943) have shown that the glomerular filtration-rate falls during anæsthesia, and this in itself will reduce the sodium excretion (Chalmers et al. 1952). But the glomerular filtration-rate rapidly returns to normal after operation (Habif et al. 1951, Ariel and Miller 1950), and the period of depression may not therefore account for more than a part of the retention observed. Moreover, the excretion of potassium which has been shown to take place on the day of operation is one of the most characteristic features of the onset of adrenal stimulation (Bartter and Fourman 1951), and it is difficult to believe that the latter plays no part in causing this sodium retention. It therefore seems likely that early sodium retention is due in part to hæmodynamic factors and in part to adrenocortical release.

Late sodium retention occurs at a time when the sweat sodium concentration is falling (Johnson et al. 1950); and this again is known to result from the salt-retaining action of corticoids, suggesting that the late retention is cortical in origin. If, then, cortical release is partly or wholely responsible for both periods of sodium retention, it is difficult to see why they should ever be separated by a day of negative balance. The most likely explanation appears to be that the adrenal salt-retaining mechanism becomes fully effective only after a day or two, and that the early sodium retention is largely due to other factors. The whole postoperative disturbance of salt and water metabolism is probably due to three factors—namely, a release of antidiuretic hormone, renal hæmodynamic factors, and adrenocortical release; during the first 48 hours after operation the effect of the last is overshadowed by that of the first two, but becomes clearly apparent thereafter.

As mentioned above, potassium deficiency by itself can cause sodium retention, and there is little doubt that this has been partly responsible for the postoperative retention observed by many previous workers. However, potassium deficiency is not the main cause of postoperative sodium retention; it merely augments it.

It is possible that the period of relative starvation following operation might in itself cause sodium retention. Newburgh (1942) found that some cases of obesity failed to lose weight initially when put on a low-calorie intake, and suggested that salt and water retention was responsible for this. However, this only occurred in some cases; and Duncan et al. (1948), who gave a salt mixture to 2 patients during starvation, observed a negative sodium balance under these circumstances.

It is not clear whether the water and sodium are retained in the extracellular or intracellular compartment. Our data are insufficient to allow calculation of the exact amount of water retained; but a reasonable estimate could be made in many cases, and in all of these correlation with the sodium balance suggested that the retention of both was largely extracellular. Moreover, the fact that the chloride retention was usually greater than that of sodium also suggests that the retention was in the extracellular space. Indeed this discrepancy between the sodium and chloride balances even suggests that there may be a shift of sodium from the intracellular to the extracellular compartment. This hypothesis—that there is a considerable enlargement of the extracellular space after operation—is consistent with the findings of Lyon et al. (1949) and of other workers that the thiocyanate space is greater at this time. In addition, Levitt and Bader (1951) have shown that the administration of either A.C.T.H. or cortisone leads to an enlargement of the extracellular fluid volume, with a shift of sodium from the cells.

There are important practical applications of this work, which will be discussed in detail elsewhere. In planning the postoperative intake it must be borne in mind that the patient's ability to excrete salt is greatly reduced in this period, and that there is a similar inability to excrete water during the first 24 hours after operation.

Either a bronchodilator—e g, isoprenaline—alone or physiotherapy regimen (postural drainage and vibratory and clapping percussion) alone was not more effective than breathing exercises in reducing atelectasis in 160 patients undergoing operations for inguinal hernia or for partial gastrectomy

It is concluded that postural drainage with vibratory and clapping percussion to the chest wall and a bronchodilator in combination are necessary for the prevention of postoperative atelectasis The reasons for this are discussed

We wish to thank the members of the research grants committee of the Middlesex Hospital, and the surgeons, anæsthetists, and members of the department of physical medicine for their coöperation, Dr C G Whiteside for his reports on the X ray films, Prof Alan Kekwick for much help and encouragement, and Dr John Friend for reading the manuscript

PRACTICAL PENICILLIN

Robert I Cohen
M B Lpool, F R C S
LATE SENIOR SURGICAL REGISTRAR, UNITED LIVERPOOL HOSPITALS

It is hoped that this paper may do something to reduce the long stream of patients with minor sepsis entering the casualty departments of hospitals, shorten the time lost to the patient and the community by ill health, and be of practical help to general practitioners It is written to show that procaine penicillin in aqueous suspension is a very serviceable weapon against acute infections

Previously I showed (Cohen 1950) that 300,000 international units of procaine penicillin in aqueous suspension will almost always give an effective blood-penicillin level for twenty-four hours, and that a single daily injection of such a suspension has big advantages over the three-hourly injection of aqueous solutions of crystalline penicillin (soluble penicillin) From the literature it was clear that large doses of procaine penicillin in *oily* suspension could be given without ill effect (Thomas et al 1951), and Cannon et al (1951) stated that twice-weekly injections provided a very effective blood-penicillin level, but when these workers used an aqueous suspension they could not depend *on an effective level after twenty-four hours* In my experience, however, this objection does not apply to the suspension now widely used I have found that, after a single injection, penicillin is present in the blood for three or four days, and that this is a basis of sound treatment not only in the outpatient department of a hospital, but also, and particularly, in general practice

TABLE I—RESULTS OF TREATMENT WITH 5 ML. OF PROC PENICILLIN AQUEOUS SUSPENSION IN HOSPITAL CAS DEPARTMENT

Condition	No of cases	Length of treatment (days)			No incised	No injected more than once
		Ave	Max	Min		
Abscess						
Axillary	9 (*4 5%*)	7	13	2	4 (*44 4%*)	
Breast	2 (*1 0%*)	8	8	8	2 (*100%*)

Hand	83 (*41 5%*)	7	34	2	31 (*37 4%*)	2
Leg and foot	30 (*15 0%*)	7	13	2	5 (*16 7%*)	2
Total	200				*54 (27%)*	9

Long et al (1950) have pointed out that, in using an antibiotic, the aim should be to bring the infection under control as quickly as possible, which necessitates adequate doses This is especially important in the treatment of severe or *fulminating infections* The same workers warn against overtreating the patient when the infection is controlled, treatment should be discontinued "Remember," they say, "in most instances the response should be prompt"

TREATMENT IN HOSPITAL CASUALTY DEPARTMENT

With these precepts in view, blood-penicillin levels were estimated at the intervals shown in fig 1 after the administration of 1 5 mega-units of procaine penicillin in aqueous suspension, in these experiments 'Distaquaine Suspension' was used The injection is one of 5 ml, but this volume can be given with little or no discomfort into the triceps or the gluteal region

Having found an adequate blood penicillin level three or four days after the injection of 1 5 mega units

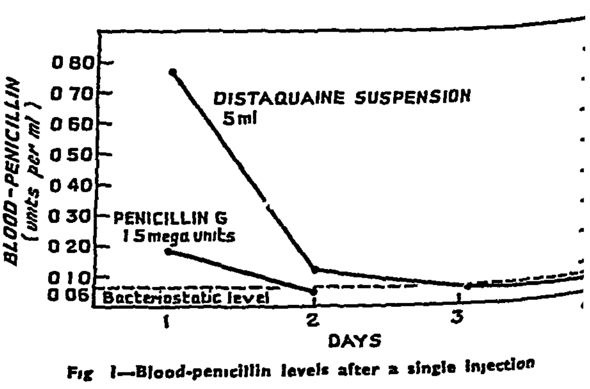

Fig 1—Blood-penicillin levels after a single injection

I—TUBERCULIN CONVERSIONS IN NEWCASTLE CHILDREN 1947–52

of ren	No. tested	No. of conversions	Total	Increase in each round (%)*
nths	960	17	17 (1·8%)	1·8
rs	900	30	47 (5·1%)	3·3
rs	810	13	60 (6·7%)	1·6
rs	800	6	66 (7·5%)	0·7

ne tuberculin testing has been done with Old reculin jelly, followed in doubtful results by an dermal test of 10 T.U. of Old Tuberculin. The ts of these tests (table I) show a conversion-rate of , at the age of 15 months, rising to 7·5% at that of ars. In table II the sample has been adjusted to the of each year and the standard error of the percentage ılated.

ıe estimate of the number of children aged less than ears tuberculin-positive in Newcastle at any given has been calculated in table III from a percentage ulated for the middle of each year. The range ıin which the true figure may fall is, however, siderable; and, though we give 1020 as an estimate, variation may be anything from 720 to 1330. It is to say, however, that in Newcastle at present nearly of the children have been infected by the end of r second year and between 7% and 8% at the end heir fifth year.

ur figure may be checked by the data published by Medical Research Council (1952). In that report children were all of school age attending State ools and not a sample of the population, and the erculin tests used were rather different—a modified ur-paper technique was used with tuberculin jelly as a t test, and as a second test 100 T.U. of Old Tuberculin s injected intradermally. These tests are both stronger ın ours and may perhaps have given a positive ction when the 10 T.U. or the application of Old berculin jelly to the cleansed skin would not have ıne so. In the two areas nearest to Newcastle, Durham tanley U.D.) had 10·6% positive reactors in the sixth ar, and Leeds 9·8%. From Hull Hardy (1950) has ported that, in a tuberculin survey of 4000 children ged 5–15, 10% were positive at the age of 5 years. e does not, however, state the composition of the oup examined or the test used. Parkes (1952), using flour-paper technique, found in Wolverhampton during 50 6·3% positive in 2923 school entrants tested with lly.

BLE II—TUBERCULIN CONVERSIONS IN NEWCASTLE CHILDREN

ge of ildren (yr.)	Tuberculin-positive (%)	Standard error of percentage	Range ± 2 S.E.	
			Minimum	Maximum
1	1·4	0·4	0·2	2·2
2	3·2	0·6	2·0	4·4
3	5·1	0·7	3·6	6·6
4	6·7	0·9	5·0	8·4
5	7·5	0·9	5·7	9·3

We therefore consider that our figure of conversion-ıtes based upon repeated testing of the same unselected ımple of the infant population of the city gives a valid asis for our estimate that 4% of all children aged less ıan 5 years were infected—about 1020 in a population f 25,000 children.

MORTALITY AND MORBIDITY FROM TUBERCULOSIS

After a careful and thorough search of all records we raced 258 of the estimated number of 1020 children ho had acquired primary infection with tuberculosis. Thus only 1 in 4 of the children were traceable at hospital or in tuberculosis contact clinic in a city where there is constant interest in childhood tuberculosis, all children in hospital have routine tuberculin tests, and all children aged less than 5 years who are in contact with a known case of tuberculosis in the family are carefully examined.

The 258 children were found through the following sources: 98 notified cases, 21 hospital cases not notified, 134 household contacts from observation clinics, and 5 other outpatients. In 201 we knew, and in another 30 cases could infer, the source of infection. All but 3 of the notified patients were in hospital, and it is unlikely that we would have missed children with recognised tuberculosis. Unless, therefore, which again is unlikely, a substantial number of children were ill and untraced, about 750 children passed through their primary infection in these five years either without illness or with so slight or temporary a disturbance of health that its nature remained undetected.

TABLE III—ESTIMATED NUMBER OF NEWCASTLE CHILDREN AGED LESS THAN FIVE YEARS TUBERCULIN-POSITIVE AT ONE TIME

Age (yr.)	No. of children	Positive at mid-point of year (%)	Estimate
0–2	10,000	1·6	160
2–3	5000	4·2	210
3–4	5000	5·9	295
4–5	5000	7·1	355
Total ..	25,000	4·1	1020

The 258 tuberculin-positive children comprised two very distinct groups: 117 admitted to hospital, most of whom were notified; and 141 who remained under outpatient supervision, few of whom were notified. More than half (170) of the 258 had been found tuberculin-positive during attendance at the contact clinics.

To the end of 1951, 39 of the 258 had died, 36 (14%) certainly from tuberculosis, and in the remaining 3 there was a strong presumption of tuberculosis. In all the fatal cases, except 4 caused by progressive primary lung lesions, the immediate cause of death was either tuberculous meningitis or miliary tuberculosis. When considering this mortality we should remember that 1949 was the first year in which streptomycin was generally available and B.C.G. vaccination started. Today this mortality of 3·5% within two years would be lower but not by more than half, and even with streptomycin available the present mortality-rate would be about 2% of children infected at less than 5 years of age.

The lesions found in the 258 children are set out in table IV, but the numbers under the various headings are obviously not of equal value or importance. Whereas we are not likely to have missed more than one or two, if indeed any, cases of miliary spread, meningitis, or bone disease, there must have been many cases of "fever of onset," temporary ill health, or failure to gain weight or loss of weight, and perhaps a few of conjunctivitis, wheezing, or even "silent" pleural effusion in young children who did not reach the hospital outpatients or

TABLE IV—LESIONS PRESENT IN 258 TUBERCULIN-POSITIVE CHILDREN AGED LESS THAN 5 YEARS

Progressive chest lesions	8
Bone and joint lesions (including 4 cases developing after tuberculous meningitis or miliary tuberculosis)	16
Miliary tuberculosis	23
Tuberculous meningitis	35
16 children had both miliary tuberculosis and tuberculous meningitis, making 42 children affected	

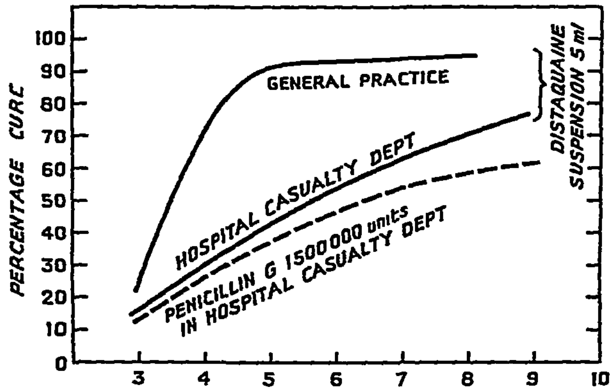

Fig 2—Percentage rates of cure

with a septic finger) had the finger opened with a needle in the surgery All the other cases treated resolved without requiring the help of hospital treatment, and 91 of the 100 cases followed up were cured at the end of five days with one injection and salt-water dressing (see table IV)

The relief on the children's faces, when they were told one injection only would be required, was sufficient reward in itself A large number of ear cases were treated Some had been discharging for months, these dried up but required more than one injection Single-injection therapy, as shown by tables I, II, and III, is not adequate in all cases Should injections subsequent to the first be necessary they should be given every fourth day

Fig 2 and table IV show the day-by-day percentage cure in the three divisions of this trial

COMMENT

The established facts show how important it is to begin treatment early, and it emphasises that the place to begin treatment is in general practice It is better to give an unnecessary injection than to wait and see whether the infection will clear up without it

When all clinical requirements are fulfilled, cost becomes important The cost of this single-dose therapy compares favourably with that of the dressings, ointments, &c, so often prescribed for the types of infection treated in these trials Of the utmost importance is the freeing of the casualty departments of busy general hospitals from the need to attend to many chronic and difficult infections It is important to the nation that workers be able to return to work quickly after absences due to minor acute infections, but the social aspects of these trials need not be emphasised in what is essentially a clinical report

SUMMARY

Trials showed that 1 5 mega-units of procaine penicillin in aqueous suspension would maintain an effective blood-penicillin level for three or four days, and that the same dose of crystalline sodium penicillin G (benzylpenicillin sodium salt) in aqueous solution was effective for twenty-four hours only

Clinical trials showed that this dose of the aqueous suspension of the procaine salt was more effective in combating infection in the outpatient department of a general hospital than was a similar dose of crystalline sodium penicillin G in aqueous solution

Moreover, a single injection of 1 5 mega units of the procaine-penicillin aqueous suspension, given by the general practitioner when the patient was first seen, led to cure of 91 cases out of 100 by the fifth day Only 1 case out of 135 required incision at hospital

In addition to the facts that only 1 patient had to go to hospital and that only 1 patient's finger, that of a baby, had to be opened, the time factor should be sidered The patients are returned to work quickly, and in some cases may altogether avoid ' ping off" Patients themselves can judge whether septic lesion is getting worse, and they can be asked report back if the necessity arises The doctor's is saved, for an injection of this type can be given in couple of minutes

My thanks are due to Mr R Kennion, Mr J B and Mr S V Unsworth, surgeons of the United Hospitals, on whose patients I have undertaken this to Dr J Sytner and his partners for allowing me the facil of their general practice, to the Distillers Company chemicals) Ltd, for the use of their laboratories and for penicillin preparations used in this work, and to Mr Grainger for his invaluable help in the laboratory

SIMULTANEOUS AORTIC AND AXILLARY EMBOLISM

SUCCESSFUL TREATMENT FOLLOWED BY MITRAL VALVOTOMY

E. G HARDY
M B Aberd, F R C S E
LATE SENIOR SURGICAL REGISTRAR

CHARLES NOON
O B E, F.R.C.S
SENIOR SURGEON

NORFOLK AND NORWICH HOSPITAL

WE report this case because no similar successful multiple embolectomy seems to have been published, and no other case of similar ætiology seems to have been carried to a logical conclusion by subsequent valvotomy

CASE-RECORD

Mrs A, a thin, nervous, but coöperative housewife of 41 was admitted to the Norfolk and Norwich Hospital on Dec 1 1951, under the care of Dr Branford Morgan, with congestive heart failure complicating rheumatic mitral stenosis She had been admitted several times previously for similar episodes In 1945 she had had an embolic right hemiplegia, from which she gradually and almost completely recovered

The present attack of failure was typical, with a conspicuous malar flush, rapid auricular fibrillation, and signs of mitral stenosis Under medical treatment, including full digitalisation, she progressed well, and on Dec 29 she was allowed up in a chair for the first time On this day also she developed some nausea and vomiting, due probably to digitalis

On Dec 30 at about 11 A M sudden numbness came on in the left arm and leg, and shortly afterwards in the right leg also There was little pain Both lower limbs were pulseless from the groins down, and the left brachial and radial pulses were also absent Sensation and movement of all the affected limbs were much impaired Although cold and frightened, the patient was in fair general condition fibrillation was present A diagnosis was made of multi-arterial embolism, arising from the fibrillating left auricle, and surgical help was obtained within thirty minutes of the onset of symptoms

Operation

Operation was undertaken four hours after the first symptoms appeared The anæsthetic, given by Dr B G Forres was thiopentone followed by nitrous oxide, oxygen and minimal ether, with fractional doses of gallamine ('Flaxedil')

First, the inert and spastic femoral arteries were exposed in each groin and occluded with Crile clamps Then, with the patient in the Trendelenburg position the abdomen was opened through a generous left lower paramedian incision The aortic bifurcation and the few centimetres of trunk be

Fig. 1.

ineapig to the actions of metabolites injected extrallularly; that the extracellular injection of A.D.P. ay cause glycogen to be converted to glucose-1-phoshate and so diminish sensitivity; and that the simulneous extracellular injection of A.T.P. and A.D.P., preventing a shift in the A.T.P./A.D.P. balance, may event desensitisation.

In the present paper we show that, as the ratio of tracellularly injected A.T.P. to A.D.P. is increased, the esensitising action of A.D.P. is first diminished and then olished; in addition, injected A.T.P. inhibits the esensitising action of alloxan, cortisone, and dehydrocorbic acid, but not that of glucose-1-phosphate. hese facts are consistent with our hypothesis; for if T.P. has inhibited glycogen breakdown, blocking hosphoglucomutase will not increase the concentration the tissues of glucose-1-phosphate. On the other and, the concentration, and therefore the desensitising ction, of injected glucose-1-phosphate will be indeendent of these factors. Thus the results we expected n the basis of intracellular metabolism were achieved. t seems more probable that these organic phosphates, njected extracellularly into tuberculin-sensitive guineaigs, influence normal intracellular carbohydrate metaolism than that they produce a hypothetical series of harmacological coincidences associated with like effects. lucose-1-phosphate is a normal metabolite, but its ôle as intermediate in an important biological process ay mean that, unless the balance of the process is ppropriately disturbed, it is never free from the enzyme omplex; so even minute quantities introduced from utside may produce an effect out of proportion to the otal amounts involved in glycogen metabolism. It is ossible that cell permeability is increased in guineapigs ndergoing a severe tuberculin response, and that the rgument holds only for this condition. However, we onclude that in B.C.G.-infected guineapigs, glycogenoysis (glycogen breakdown), with resulting glucose-1-hosphate formation, is associated with diminished ensitivity to tuberculin; that injected A.T.P., by timulating glucolysis (glucose breakdown) and inhibiting lycogenolysis, antagonises this action and so prevents esensitisation; and therefore, that hexokinase hyperactivity and hypersensitivity on the one hand, and hexokinase hypoactivity and desensitisation on the other hand, are associated phenomena.

Fortunately, the actions of certain hormones upon carbohydrate metabolism in general, and upon hexokinase activity in particular, are not subject to the restrictions imposed by these problems of intracellular-extracellular relationship which have hitherto handicapped and confined our argument. The latter part of the present paper, is therefore devoted to a study of the actions of insulin, which stimulates hexokinase activity directly or indirectly, and of growth hormone, which antagonises it (see, for example, Wright 1952, Young 1948).

In this connection, it is noteworthy that hexokinase activity is increased in the tissues of thyrotoxic animals (Smith and Williams-Ashman 1951), and that thyroxine enhances glucose utilisation in the tissues (Mirsky and Broh-Kahn 1936) and stimulates the formation of A.T.P. (Venkataraman et al. 1950), which initiates the hexokinase reaction. In addition, thyroxine increases sensitivity to tuberculin (Long and Miles 1950, Long et al. 1951b). These facts are consistent with, and support, our present contentions.

The argument is strengthened by our findings (reported here) that growth hormone, which inhibits hexokinase activity, depresses sensitivity to tuberculin, whereas insulin, which stimulates hexokinase activity, antagonises the desensitising actions of cortisone, alloxan, and dehydroascorbic acid, but not of glucose-1-phosphate. Moreover, the compensatory phase that follows insulin hypoglycæmia—a phase for which the adrenal cortex is largely responsible (see, for example, Wright 1952)—is associated with desensitisation. As might be expected, this compensatory phase of desensitisation, like that produced by cortisone, does not occur in animals previously injected with reduced glutathione nor in ascorbic-acid-deficient guineapigs (cf. Long et al. 1951a and c). In addition, it can, like cortisone desensitisation, be prevented by injected A.T.P. In this connection, the observation of Kersley et al. (1951) that insulin hypoglycæmia is succeeded in rheumatoid arthritis by symptomatic relief comparable to that obtained with adrenocorticotrophic hormone (A.C.T.H.) is noteworthy.

From our experiments with organic phosphates and hormones, we conclude that sensitivity to tuberculin in B.C.G.-infected guineapigs depends on a balance between hexokinase-stimulating and hexokinase-depressing hormones, with the adrenal cortex controlling the metabolic process most intimately linked with sensitivity—namely, the concentration in the tissues of glucose-1-phosphate. Although part of the argument is based on results obtained with extracellularly injected carbohydrate metabolites, the remainder and major part is not subject to this limitation, and yet points to the same conclusions.

METHOD

Albino guineapigs of the Hampstead strain, weighing 350–550 g. and fed on a pelleted diet (Bruce and Parkes 1947) supplemented with unlimited cabbage, were injected with B.C.G. vaccine, and sensitivity to tuberculin was estimated by the method of Long and Miles (1950).

All drugs tested, except glutathione, growth hormone, cortisone acetate, and insulin, were dissolved in 1 ml. of normal saline and injected subcutaneously two hours before the tuberculin. Reduced glutathione was dissolved in gas-free distilled water and adjusted with sodium bicarbonate solution to pH 6; approximately 150 mg. per kg. body-weight, in a volume of 2 ml., was injected intraperitoneally two hours before the tuberculin. Cortisone acetate was suspended in 1 ml. of normal saline and injected six hours before the tuberculin. Growth hormone, partly dissolved, partly suspended, in 1 ml. of normal saline, was injected in the doses, and at the time-intervals, detailed in the experiments. Insulin was dissolved in 1 ml. of normal saline and injected subcutaneously at the time-intervals detailed in the experiments; the batch did not contain detectable quantities of hyperglycæmic factor. Animals treated with insulin received no food on the day of the experiment.

In this connection it is interesting to note that Ewing (1950) examined the abdominal aorta and iliac vessels from his second case on the patient's death 12 months later the terminal aorta and common iliac vessels were much narrowed and blocked by clot, high enough to include the origin of the inferior mesenteric artery Section of the thrombus suggested that it was "probably over 6 months old"

In spite of the failure to restore the pulses in the present case, the operation cannot be branded as useless or unnecessary McClure and Harkins (1943) believed the prognosis without operation to be nearly hopeless Rothstein (1935) found the recovery-rate to be only 4% from conservative measures as against 32% from surgery Ewing (1950) thinks that even these few successes without surgery are probably cases in which either the diagnosis is doubtful or the clot has broken up and passed distally In our patient the circulation in the lower limbs is so adequate that the internal iliac arteries may well have remained patent, thus giving a circulation via the gluteal vessels

The case for removing the axillary embolus rests on less secure grounds In healthy people the third part of the axillary artery can usually be interrupted without jeopardising the limb Nevertheless the clot here, as in the aorta, was several centimetres long, and must have covered the mouth of at least one major branch The brisk retrograde bleeding that followed its removal lent support to the idea that the procedure would materially enhance the safety of the limb by improving the collateral circulation It is also felt that the main vessel might for a short time maintain the nutrition of the limb while the collateral channels were developing Had the patient's condition been too precarious to allow axillary embolectomy, however, conservative measures would have had a fair chance of success

Prognosis and After-treatment

Besides the 27 successful aortic embolectomies reviewed by Taylor (1951) 2 have been reported by Ewing (1950), 1 by Dalgleish and Taylor (1951), and 1 by Shipman and Goodwin (1951) The present case brings the total to 32

Of the 32 patients at least 13 are known to have died within 3 years of operation, and several others have not been followed up This major vascular catastrophe occurs almost always in patients with crippling cardiovascular disease, by which the end-result should be measured Some workers have attacked the problem of recurrent arterial embolism by operations on the left auricular appendage, where the embolising thrombus often forms The feasibility of amputation of the appendage in dogs was demonstrated by Hellerstein et al (1948) The operation was performed in man by Madden (1949) Of his 2 patients one survived, but the other after a successful aortic embolectomy, died 9 days after the second operation Baronofsky and Skinner (1950) simplified the operation by substituting ligation for resection of the appendage, and published 3 cases without fatality These operations, however, do nothing to improve the basic heart condition According to Taylor (1951) 78% of the successful aortic embolectomies have been in cases with mitral stenosis or with auricular fibrillation, or with both On general principles one would expect the more recently developed operation of transatrial mitral valvotomy to have a place in the cases with mitral stenosis In their report on mitral valvotomy Baker et al (1952) say

> "We now regard such a history (of embolism) as one of the indications for valvotomy in the hope that less stasis in the atrium will discourage clotting"

It was on precisely such reasoning that the present case was referred to the cardiac surgical unit Many more cases and some years' observation will be necessary to determine whether the prevention of recurrent by such means is anything but a pious hope

SUMMARY

A case is described of simultaneous embolism axillary artery and at the aortic bifurcation

Multiple embolectomy was successful in sam patient and the affected limbs, and some po technique are discussed

Mitral valvotomy was subsequently performed where, with a view to improving the cardiac and preventing further embolism

Our thanks are due to Dr Branford Morgan for the case and for help in the postoperative management

THE METATARSAL FORMULA IN RELATION TO MARCH FRACTURE

C H Barnett
M A, M B Camb, F R C S

J R Napie
M R C S

LECTURERS IN ANATOMY, ST THOMAS'S HOSPITAL MED
SCHOOL, LONDON

THE relative protrusion of the first and second tarsal bones in the normal human foot is a much disp subject Morton (1927) is of the opinion that relati "shortening" of the first metatarsal is abnormal and potent source of foot disorders A similar view has be advanced by Bruce (1937), who states that in the norm foot the head of the first metatarsal is "on the sa transverse plane, or even a little more distal, than t of the second" On the other hand, Wood Jones (19 in discussing the metatarsal formula, denies that t so called "short" first metatarsal is in any wa abnormal, and maintains that "it is normal in man f

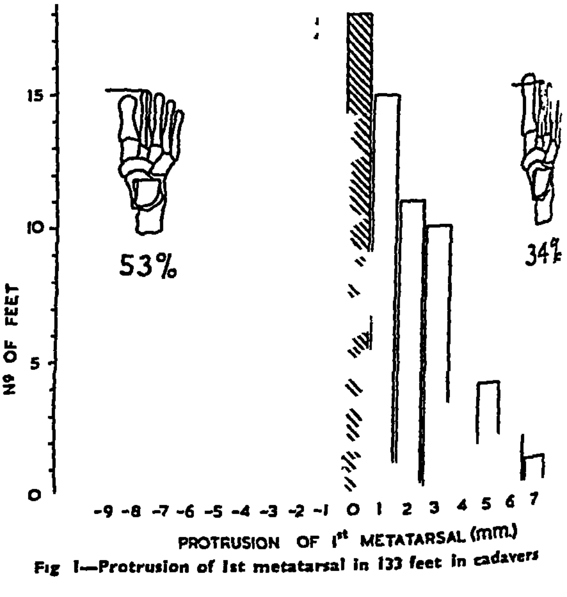

Fig 1—Protrusion of 1st metatarsal in 133 feet in cadavers

. This compensatory hyperglycæmic phase is attribut-
e to hyperactivity of adrenal cortex and medulla
, for example, Wright 1952), and consistent with
s view, the desensitisation associated with it did not
ur in guineapigs previously injected with reduced
tathione, or in ascorbic-deficient animals (experi-
nt 3) (cf. Long et al. 1951a and b). It is noteworthy
t, as in cortisone-treated animals, injected A.T.P.
used a significant increase in sensitivity (experiment 3)
ble II).

The immediate effect of insulin, during the phase of
poglycæmia, is shown consistently by a slight increase
sensitivity. In only one experiment was this increase
tistically significant; the result given in experiment 3
typical. Insulin, by stimulating hexokinase activity
d increasing glycogen storage, might be expected,
the basis of our hypothesis, to antagonise desensitisa-
n by *cortisone, alloxan, and dehydroascorbic acid.*
sulin is thought to stimulate phosphorylase and so
omote the conversion of glucose-1-phosphate to
ycogen (see, for example, Young 1948). Such an effect
as not apparent in our experiments, extracellularly
jected glucose-1-phosphate proving fully active in
nimals treated with insulin (experiment 4). Insulin
evented desensitisation by alloxan and dehydro-
corbic acid, and significantly increased sensitivity in
rtisone-treated animals (experiment 4) (table II).

Presumably this effect, like that of A.T.P. under similar
nditions, is due to the hexokinase-stimulating activity
insulin, reinforced by glucose derived from protein
nder the influence of cortisone.

owth Hormone

Growth hormone antagonises insulin and depresses
xokinase activity (see, for example, Young 1948).
proved a powerful desensitising agent in a dose of
) mg. per kg. body-weight, increasing in effectiveness
p to twelve hours, beyond which time it was not tested.
n-cabbage-fed but not in ascorbic-acid-deficient guinea-
igs, it had a synergistic action with cortisone and also
lloxan (experiment 5). The desensitising action of
rowth hormone is not influenced by injected A.T.P.,
educed glutathione, or insulin; or by ascorbic-acid
eficiency in the diet (experiment 6) (table II), all of
hich, as already stated, prevent cortisone desensitisa-
on. The experiments quoted here were carried out with
single large batch of growth hormone provided by
essrs. Armour; they were confirmed with a highly
urified preparation provided by Prof. F. G. Young.
his latter preparation, tested at eight hours, had
pproximately twice the desensitising potency of the

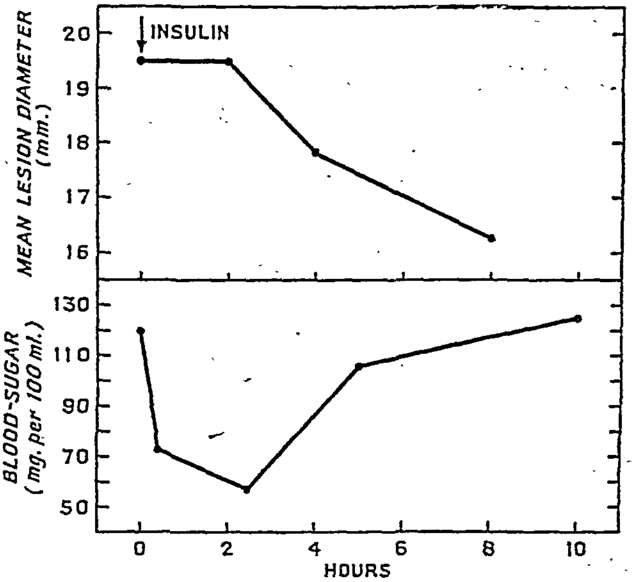

Fig. 3—Effect of insulin on blood-sugar level and tuberculin hypersensitivity.

Armour preparation, possibly owing to its greater solubility.

DISCUSSION

The idea that insulin, the adrenal steroids, and growth hormone influence hexokinase activity is not new. The Coris suggested, on a basis of in-vitro experiments, that the adrenal steroids and the anterior pituitary inhibit hexokinase activity, and that insulin antagonises the actions of these hormones and so allows hexokinase activity to be resumed (Cori and Cori 1946, Colowick et al. 1947). But the Cori contentions are at variance with the facts. Excess of anterior pituitary and adrenocortical hormones are known to influence blood-sugar in a manner comparable to that associated with insulin deficiency. But insulin, which would be expected from the Cori hypothesis to be inactive in the hypophysectomised or adrenalectomised animal, shows instead enhanced activity. It seems improbable that adrenal steroids, in times of emergency, would stimulate the formation of glucose from protein, only to block its oxidation and moreover the oxidation of glucose from other sources. The idea that growth hormone inhibits hexokinase activity is more acceptable and does not depend only on in-vitro evidence. Growth hormone increases the formation of tissue protein, a process associated with a decrease in the amount of amino-acids in the blood and a decrease in nitrogen excretion in the urine; serum alkaline phosphatase and cell lipids are increased in amount, but reserve fat is decreased; calcium and phosphate retention are associated with growth of bone.

These build-up processes, particularly of protein, depend upon the maintenance of a normal level of blood-glucose. If this level falls, adrenal steroids facilitate protein conversion to glucose; thus growth hormone, by blocking hexokinase activity, would be expected to maintain the blood-sugar level, prevent protein breakdown, and assist growth. In the present paper, we show that the desensitising actions of growth

On the completion of the pregnancy, the result would be classified by the pædiatric staff of the hospitals, or by the medical officers of the maternity and child-welfare service, as "normal stillbirth," "deformed stillbirth," "normal live birth," or "deformed live birth"

A total of 989 births were recorded in this way (table I)

Table II sets out in slightly more detail the 164 births to mothers who had influenza it shows the month of pregnancy in which the infection occurred

Although the incidence both of stillbirth and of deformed live birth is rather higher in the "influenza" group than in the control group the difference is in each case slight and cannot be regarded as significant.

CONCLUSION

A group of mothers who had influenza (A-prime type) in the early months of pregnancy, and a similar group who did not have influenza, were observed during pregnancies

The findings do not suggest that influenza in the months of pregnancy adds appreciably to the stillbirth or fœtal abnormality

This report could not have been made without the cooperation of the staffs of the hospitals concerned and of maternity and child welfare service of Belfast Corpora who compiled the bulk of the records The investigation made under the general direction of Prof F M B Prof C H G Macafee, and Prof A C Stevenson Tab. and II were prepared in the Department of Social Preventive Medicine, Queen's University, Belfast

BRONCHOPNEUMONIA

ent (Muller et al. 1929, Howkins 1948), and the judicious use of abdominal binders (Churchill and cNeil 1927). Opiates, moreover, reduce the desire cough.

Secretion in the smaller bronchi is normally moved the activity of the ciliated bronchial epithelium ackson and Jackson 1933, Boyd et al. 1943). Anæs-ietics, lack of oxygen, excess of carbon dioxide, and creased viscosity of the bronchial secretion reduce liary activity (Hill 1928, Negus 1933), thereby favouring ie retention of sputum in the smaller bronchi.

Congestion of the bronchial mucosa and bronchial iasm reduce bronchial calibre. Under these conditions ry small amounts of secretion may produce bronchial clusion and atelectasis. Bronchial spasm may occur the induction period if an endotracheal tube is introiced into an insufficiently anæsthetised patient, and hen anæsthetics such as cyclopropane (Rovenstine 942) and barbiturates (Burstein and Rovenstine 1938) e used. It may be caused during the operation, rough rough handling of the viscera and traction on ie mesentery (De Takats et al. 1942), or after the ieration if there is severe pain (Lucas 1950). Patients ith chronic bronchitis are especially liable to develop onchospasm after operation. Congestion of the onchial mucosa may be produced by irritant anæsietic vapours or by the aspiration of irritant-material ito the lungs. The inhalation of stomach contents iay follow frank vomiting, but of greater danger is ie silent regurgitation which may not be noticed until ie mask is removed at the end of the operation (Culver ; al. 1951).

The amount of bronchial secretion is increased by ifection and irritation of the bronchi and by stimulaion of the secretory glands of the bronchi reflexly via he vagus (Florey et al. 1932, De Takats et al. 1942). n increase in the viscosity of bronchial secretion resultig from dehydration, chronic bronchitis, or large doses f atropine (Thomas et al. 1938) or scopolamine (Hibma nd Curreri 1942) is also an important factor in the roduction of atelectasis; for, when the viscosity of ronchial secretion is increased, secretion is not removed from the smaller bronchi by ciliary movement, or from the larger bronchi by coughing.

Thus, after operation, the normal mechanisms for the clearance of bronchial secretion are seriously impaired and changes in the bronchial secretion may take place. For these reasons sputum is retained in the lungs, leading to atelectasis.

Therefore the prevention of postoperative atelectasis depends essentially on preventing retention of sputum, and on recognising those cases in which this is especially likely.

We have found that the risk of a patient's developing atelectasis is high when one or more of the following factors is present:

(1) A history of even minimal bronchitis—e.g., recurrent productive winter cough.

(2) Clinical or radiological evidence of bronchitis.

(3) An infection of the upper respiratory tract in the 14 days preceding the operation.

(4) Abdominal operations, especially partial gastrectomy and cholecystectomy, and repair of inguinal hernia.

Thus atelectasis is particularly liable to develop in patients who, by reason of chronic infection or irritation of the bronchial tree, produce a viscid bronchial secretion. Smokers and elderly men are high-risk cases because they commonly have bronchitis, and those undergoing abdominal operations because they have most difficulty in expectorating secretion after operation.

METHODS

The present regimen was developed because the routine measures in this hospital—procaine penicillin and breathing exercises before and after operation—were failing to prevent postoperative atelectasis (Palmer and Sellick 1952a). The method we now adopt consists in (*a*) postural drainage with vibratory and clapping percussion and (*b*) inhalation of isoprenaline before and after operation. Isoprenaline has a powerful bronchodilator and vasoconstrictor action on the bronchial mucosa, and it is given to overcome the spasm and the congestion of the bronchi which are thought to be responsible for the rhonchi often heard after the opera-deficiencies and infections There are useful appendices on colloid chemistry, isotopes, thermodynamics, and acids and bases One of the most valuable and novel chapters is that on genetics, the biochemical implications of which are fast expanding, and the authors are not afraid to speculate on the relation of protein structure to the mechanism of memory and imagination, or to discuss smell and taste in terms of enzyme inhibitors The basal metabolic rate in cases of Simmonds's disease is erroneously given as "minus 50 or less," and leukæmia is omitted from the list of conditions with a raised blood uric acid, but there is little else to criticise and much for the clinician to respect and value in this book

Gynäkologische Strahlentherapie

Indikationsstellung, Methodik und Ärztliche Betreuung Dr Med Richard Kurt Kepp, professor of obstetrics and gynæcology, University of Gottingen Stuttgart Georg Thieme 1952 Pp 232 DM 26

This book from the gynæcological department of Gottingen University gives a long and detailed account of the radiotherapeutic methods used in many benign and malignant conditions

The first section deals with menopausal and premenopausal hæmorrhage and lays emphasis on two different effects—one obtained locally by the irradiation of the endometrium, the other produced by the radiation received by the ovary—and gives techniques designed to obtain one or the other effect Several techniques not in ordinary use in this country are described, such as irradiation of the hypophysis for menopausal symptoms attributed to hormonal disorder, using two fields 6×8 or 8×10 cm., and giving doses of 150–200r on two or three occasions with a further course after 3–6 months Other endocrine glands are also irradiated to alter their activity, and excessive bleeding in young girls is treated by irradiation of the spleen

With malignant disease of the uterus, operation is usually chosen for patients whose tumour is in a favourable position When radiotherapy is preferred much reliance is placed on intracavitary treatment with X rays generated at 60 or 100 kilovolts The method is ingenious, and if the vagina is roomy and not severely distorted by tumour a good distribution of the radiation can be obtained For the treatment of cancer of the uterine body the uterus is packed with radium tubes Carcinoma of the vulva treated by radiation receives fractionated superficial X radiation, and fast electrons generated at 4 MeV are beginning to be used as an alternative Cancer of the breast is included because it is regarded, in Germany, as coming within the province of the gynæcological department Both preoperative and postoperative radiation is used, mainly with two tangential fields to the breast area and with single fields to axilla and supraclavicular fossa, and palliative techniques are used for inoperable cases There is a useful chapter on the treatment of post radiation complications, but there are no statistics giving the results obtained by the use of the methods described There is a long bibliography.

Psychosurgical Problems

Editor Fred A Mettler, M D, professor of anatomy, College of Physicians and Surgeons, Columbia University London Routledge & Kegan Paul 1952 Pp 357 42*s*

This is a companion volume to the Columbia Greystones Associates' earlier report on selective partial ablation of the frontal cortex Here the results of cortical venous ligation, thermocoagulation of the cortex, surgical thalamotomy, and transorbital lobotomy are considered Besides reviewing the over all psychiatric results, attempts were made to study changes in general medical condition, including autonomic functions, the neurological state, detailed psychometric tests, and psychological functions such as memory, learning, "attitude," and certain perceptual and motor abilities Apart from the clinical psychiatric sphere, few changes were observed—except for transient neurological disorders, following venous ligation The fact that this evidence was negative implies no criticism of the work, because assessment of this kind of therapy must of course, call for much negative finding The length and method of recording it, however, seem pretentious and out of proportion to the results It is on the whole a more disappointing volume than the preceding one, though it few useful facts for those who are prepared to wakefully its wastes of turgid prose

Abraham Trembley of Geneva

Scientist and Philosopher, 1710–1784 John R M A, D PHIL, D SC Oxfd, lecturer in zoology, U of Oxford London Edward Arnold 195 35*s*

British Encyclopædia of Medical Practice (2nd London Butterworth Medical Publications 1952 Vol Pp 718 Vol 12 Pp 738 65*s* each)—The las volumes of their task completed in good time for a Chr breather, the general editor, Lord Horder, and his sultant and associate editors will have had a little which to stand back and look at twelve sparkling go red volumes on the shelf, and to receive the congratu they and their contributors have earned so well The pair round off the dozen and the alphabet by goin rheumatic infection (an article by Dr Douglas H to yellow fever (by Sir Philip Manson Bahr), the editors extracted all Z's secrets under earlier letters A co analytical index is to follow (each volume already has its individual index), and this will put the finishing touch work of high merit

The Autonomic Nervous System (3rd ed Lon Henry Kimpton 1952 Pp 569 90*s*)—It is eleven since the last edition of this standard work on the auto nervous system, by Dr James C White and Prof Re H Smithwick, was published In this period early enth hopes about the value of extensive sympathectomies in treatment of hypertension have been modified, and experience has clarified the position of sympathectom causalgia In this third edition, the two original authors been joined by Dr Fiorindo A Simeone The observatio the intervening years are fully considered, and the au besides dealing with the disorders in which operation autonomic nervous system may be of value, and with technical details of operation, fully discuss anatomical physiological factors, and assess the value of drug trea in modifying autonomic activity

German-English Medical Dictionary (New York London McGraw Hill 1952 Pp 586 102*s*)—I Louis De Vries, who holds the chair of modern langua Iowa State College, is an old hand at compiling Ger English dictionaries Ably supported by medical exp has set about this latest work with a zest Some p we are told, get by well enough with altogether 400 but in this technical dictionary *Aal* is separated from *plasma* by 40,000, and even this, Professor De Vries in a preface, may not be enough Unhappily the p the book will be more than enough for most woul translators

DISCUSSION

Many factors are involved in the production of post-ative atelectasis (Band and Hall 1931, Brock 1936). have grouped them together in table I to provide etter understanding of the way each acts in causing retention of bronchial secretions.

We found that isoprenaline and postural drainage with ratory and clapping percussion together prevented electasis, but that either singly was less effective.

We think this is because changes in bronchial calibre, deficient expulsive mechanism, and changes in bronchial cretion are present in most high-risk patients after eration, and that, unless treatment is directed to the lief of these factors simultaneously, atelectasis is not evented.

When the physiotherapy regimen (postural drainage nd vibratory percussion) is given alone, secretion does ot get to a part of the lung where the cough reflex is icited. because spasm and congestion of the bronchi old the secretion in the peripheral parts of the lung. When spasm and congestion of the bronchi are relieved y isoprenaline, secretion is brought to the larger bronchi hen the patient is tipped, and it is removed by coughing.

Isoprenaline alone fails to prevent atelectasis, because, lthough spasm and congestion are relieved, secretion not brought to the larger bronchi where coughing is ffective in its removal.

This concept is supported clinically by the following ase:

A man, aged 50, was admitted in April, 1952. for a partial astrectomy for chronic duodenal ulcer. He was a heavy moker and had chronic bronchitis and emphysema. He was treated before the operation with postural drainage and ibratory percussion, with improvement in the productive ough. This treatment was continued postoperatively, but ittle or no sputum was produced, and radiography of his hest twenty-four hours after the operation showed an area f atelectasis at the left base. There were generalised onorous rhonchi and prolonged expiration. When the ostural drainage and vibratory percussion were repeated fter the inhalation of isoprenaline, 4 oz. of viscid mucoid putum was produced, and the area of atelectasis expanded.

TABLE III—RESULTS OF TREATMENT OF TWO GROUPS OF UNSELECTED PATIENTS

Group	No. of patients	No. with segmental atelectasis	No. with productive cough for 1 week or more
E	90	8 (8·9%)	0
O	90	39 (43·3%)	30 = 33·3%
		$\chi^2=27{\cdot}69$ $n=1$ $P<0{\cdot}001$ Significant	

Although all these main mechanisms operate in most ases, rarely one factor may be predominant. Atelectasis as been noted during operation (Cassells and Rapoport 1944), and the bronchoconstrictor and bronchosecretory reflexes described by De Takats are probably responsible. These reflexes may also explain those cases in which no occlusion of the bronchial lumen is found at necropsy.

Bronchial secretion after operation is often extremely viscid. A reduction in viscosity of the bronchial secretion aids removal from the lungs by increasing ciliary activity. Isoprenaline renders the bronchial secretions more fluid in asthmatic patients (Gay and Long 1949), and we are undertaking experiments to determine whether isoprenaline reduces the viscosity of the bronchial secretion in patients after operation.

Baker et al. (1951) used intravenous sodium iodide twice daily to prevent atelectasis and reported successful results. Iodides increase bronchial secretion and reduce its viscosity (Basch et al. 1941), thereby facilitating expectoration. Atelectasis did not occur in any of 100 consecutive patients treated prophylactically before and after operation by this method, but the risk of atelectasis was not great in all these cases. for in 58 the operation did not involve laparotomy. Moreover, only severe degrees of atelectasis were considered.

We have found this treatment of value where the bronchial secretion is extremely viscid, but its routine use is not advised, for the copious secretion produced by sodium iodide may, in the presence of an ineffective cough reflex, lead to retention of sputum and atelectasis.

We favour the use of steam inhalations in conjunction with isoprenaline and postural drainage where the secretion is extremely viscid, because steam reduces the viscosity of the bronchial secretion (Basch et al. 1941) without increasing the amount.

TABLE V—COMPARISON OF RESULTS OF DIFFERENT TREATMENTS IN FOUR GROUPS OF UNSELECTED PATIENTS

Group no.	No. of patients	No. with segmental atelectasis
1	40	15
2	40	4
3	40	13
4	40	17
		$\chi^2 = 11{\cdot}74$ $n = 3$ $P<0{\cdot}01$ Significant

SUMMARY

A deficient expulsive mechanism, reduction in bronchial calibre, and quantitative and qualitative changes in bronchial secretion are considered to be of great importance in leading to retention of sputum and the development of atelectasis in patients after operation.

A regimen for the prevention of postoperative atelectasis is described. This consists in the inhalation of isoprenaline and postural drainage with vibratory and clapping percussion to the chest wall before and after operation.

The incidence of atelectasis in 90 patients undergoing abdominal operations who were treated by this regimen was 9%, compared with 43% in 90 similar patients treated with breathing exercises before and after operation. All the patients received procaine penicillin before and after operation.

TABLE IV—COMPARISON OF FOUR DIFFERENT GROUPS OF UNSELECTED PATIENTS

with assisted postural drainage Their well-designed trial leaves no doubt that these measures largely *prevented postoperative radiological* change and productive cough They were applied before operation until no more sputum could be produced, thus no patient was operated on until any bronchitis present had subsided Since postoperative chest complications are uncommon in patients who are completely free from cough before the operation, one wonders how far the success of these measures is due to their preoperative use and how far they affect the established condition when applied later But PALMER and SELLICK did not set out to answer these questions, which have theoretical as well as practical implications

While nearly everyone agrees that a combination of viscid sputum and reduction of respiratory effort and cough by pain or opiates is the cause of the bronchial obstruction, the precise timing and course of events is still uncertain The term "atelectasis" is used rather vaguely by many radiologists Certainly many shadows so reported are due to pneumonia in a moderately shrunken area of lung, rather than to absorption of air alone, and one may sometimes see typical "jib" shadows clear without re-expansion, as shown by the position of the fissures and other landmarks, leaving the area of uncomplicated collapse quite inconspicuous Indeed it seems likely that the uninfected stage of lobular or segmental collapse can be radiologically invisible Moreover, it is very unlikely that such lesions cause pyrexia or constitutional upset until infection supervenes The point of these considerations is that it is difficult to demonstrate the earliest stages of the lesions or to define the onset of the process There is some evidence that it starts earlier than is often supposed STRINGER[7] found that of 13 patients who developed radiological opacities, 5 had abnormal films as early as four hours after operation CASSELS and RAPOPORT[8] described pulmonary collapse occurring during operation, but these were instances of massive collapse producing immediate signs, and it is probable that the segment or the lobule can collapse without being noticed If in fact the blockage of the bronchus and the absorption of air commonly begin during the operation, the preoperative state and the anæsthetic technique may well be more important than the postoperative treatment A factor worth attention is the effect of anæsthetic mixtures on the rate of air absorption DALE and RAHN[9] have shown that collapse following bronchial occlusion is accelerated sixtyfold when pure oxygen is breathed in place of air The oxygen content of an anæsthetic mixture might thus determine whether a region of lung distal to a bronchial obstruction was or was not airless when the patient recovered consciousness and started to cough, and complete airlessness must greatly decrease the chance of early dislodgement of the obstruction PALMER and SELLICK's results suggest a substantial prophylactic advance, and we hope that their valuable analysis will be continued to explore further the corollaries to their encouraging news

Tuberculosis Mortality

SINCE 1850 the Registrar-General has published year by year the mortality-rate from tuberculosis in each sex by age groups Those figures reveal a great fall in the mortality in all age-groups, and most people agree that this must have been due to improved environmental conditions Apart from this general fall the most interesting feature is the change in the age-distribution, and there is now a very distinct difference between the sexes for females the death rate is greatest in early adult life, whereas for males it is greatest at about the end of working life

FROST,[1] who has since been followed by others, suggested that this late peak in males could be better understood if it was studied in relation to the earlier higher rates experienced by the same group of men when young adults, an entirely new picture emerged when the rates were studied for "cohorts" instead of calendar years or decennia This view was reinforced by SPRINGETT,[2] who showed that, if it were accepted that the mortality curve for females followed a more acutely peaked pattern, the postponement of the age *of maximum mortality of males, and not of females,* could be explained mathematically While largely accepting this reasoning, McDONALD[3] has suggested that the late peak of mortality in men is associated with environmental conditions at work He bases his view on differences between various occupational, social-class, and geographical groups in England and Wales in the present century, but he does not discuss the possible influences of "migration," not only geographically but also from one occupation to another and from one social class to another Possibly, as McDONALD concludes, environment at work is partly responsible for the present high mortality in older men, but the fact that single women engaged in employment have the same pattern of mortality as married women (though with a rather higher death rate among the employed) does not suggest that this influence can be very strong Furthermore, a century ago, when men worked under far worse conditions and their wives were for the most part at home, the greatest mortality for each sex was in young adult life

RUSSELL[4] has approached these mortality rates in a rather different way He points out that the grouped data used by previous workers, based on 10-year age-groups and decennia, are not an exact guide to the tuberculosis mortality of cohorts He has accordingly estimated the general and the tuberculosis mortality of twenty-four cohorts of females born in 3-year periods from 1851–53 to 1920–22 His results confirm the great fall in tuberculosis mortality and the general constancy of the pattern of mortality in cohorts, except when disturbed by such gross influences as the first world war and the influenza epidemic of 1918–19 He confirms also the fact, first recorded by PICKEN,[5] *that by the cohort method of analysis,* as well as by the conventional calendar-year method, the age of maximum mortality for women is passing to younger age groups RUSSELL states that previous investigations based on the cohort method of study have emphasised the dependence of pulmonary taquaine suspension, I instituted clinical trials. The lty officer on duty saw the patients, and those whom onsidered should have penicillin were given 5 ml. mega-units) of distaquaine suspension, after which lowed them up in a re-dressing clinic. The cases, fore, were not selected by me. Notes were taken 0 consecutive cases. In most cases the dressings paste of magnesium sulphate (*B.P.C.*) or saline ion for the open sepsis, and glycerin of ichthammol *.C.*) for the closed infections.

e results are shown in table I. In 191 cases one tion alone was required. Cure was effected in seven n days. In the remaining 9 cases a second injection required and was given on the fourth day of treat- t. When there is no improvement by the fourth , the organisms are probably penicillin-resistant. accords with the tenets of Long et al. (1950) that response should be prompt. Further, I believe that large dose of penicillin kills off or weakens the invad- organisms in the first few days, while the patient's bodies are being built up, with the result that, when penicillin has disappeared on the fourth day, the ent's own defence mechanisms can dispose of any aining infection.

he usual indications were followed in assessing the essity for incision; these were made when required, he belief that penicillin is given to help the surgeon not to take his place.

o see whether 1·5 mega-units of crystalline sodium icillin G (soluble penicillin) in aqueous solution would e the same effect, blood-penicillin levels were measured . 1) after injecting it dissolved in 3 ml. of distilled water. caused slightly more discomfort than did 5 ml. of the caine-penicillin suspension. The blood-penicillin levels nd suggested that excretion was slow enough to rrant a clinical trial; so 100 cases were treated with the same control being used as procaine penicillin. e results are shown in table II.

lthough a similar proportion of cases required a further ection—7% for crystalline sodium penicillin G cases npared with 4·5% for procaine-penicillin suspension— average time of treatment with crystalline sodium nicillin G was somewhat longer, and the disability ring treatment rather more severe. Œdema did not tle so quickly, pain was not relieved so rapidly, and re attendances in the outpatient department were quired.

With procaine-penicillin suspension little improvement her than the relief of pain was noted in the first twenty- ir hours. During the next twenty-four hours the lema subsided, and carbuncles that were open truded a septic core on that day or the next; those that were not open began to diminish in size and redness, the inflammation appearing to subside by resolution.

TREATMENT IN GENERAL PRACTICE

The treatment of patients reaching hospital having thus been shortened, investigation was transferred to general practice. It was hoped to treat patients on their first appeal for medical help. Through the courtesy of Dr. J. Sytner and his partners, I was privileged to attend evening surgery in a general practice until 100 cases had been discharged. This meant that 135 cases were treated, only 100 of these having reported back to be seen when cured.

Here again the choice of cases was left to others, this time to the general practitioners; and, as these attended in three consulting-rooms simultaneously in the same building, it was easy to control the cases without inconvenience to doctors or patients. This group practice is in probably the poorest part of Liverpool, the houses being overcrowded, with few amenities, and in bad repair from war damage. It was chosen for these very reasons, in the belief that this repository penicillin therapy should undergo a really stern test.

I injected 5 ml. (1·5 mega-units) of procaine-penicillin suspension into patients over one year of age, and 2·5 ml. (750,000 I.U.) into those under one year (the youngest was aged eleven days). The dressings were lint soaked in "a teaspoonful of salt to a cup of water, warm but not hot." If the sepsis was closed, glycerin of ichthammol was applied. I believe that local penicillin is without efficacy; so no penicillin was applied locally. The results are shown in table III.

Out of the 135 patients seen only 2 required incision; 1 received the incision in hospital and was healed in eleven days, the other (a child, aged fourteen days,

with assisted postural drainage Their well-designed trial leaves no doubt that these measures largely prevented postoperative radiological change and productive cough They were applied before operation until no more sputum could be produced, thus no patient was operated on until any bronchitis present had subsided Since postoperative chest complications are uncommon in patients who are completely free from cough before the operation, one wonders how far the success of these measures is due to their preoperative use and how far they affect the established condition when applied later But **Palmer** and **Sellick** did not set out to answer these questions, which have theoretical as well as practical implications

While nearly everyone agrees that a combination of viscid sputum and reduction of respiratory effort and cough by pain or opiates is the cause of the bronchial obstruction, the precise timing and course of events is still uncertain The term "atelectasis" is used rather vaguely by many radiologists Certainly many shadows so reported are due to pneumonia in a moderately shrunken area of lung, rather than to absorption of air alone, and one may sometimes see typical "jib" shadows clear without re expansion, as shown by the position of the fissures and other landmarks, leaving the area of uncomplicated collapse quite inconspicuous Indeed it seems likely that the uninfected stage of lobular or segmental collapse can be radiologically invisible Moreover, it is very unlikely that such lesions cause pyrexia or constitutional upset until infection supervenes The point of these considerations is that it is difficult to demonstrate the earliest stages of the lesions or to define the onset of the process There is some evidence that it starts earlier than is often supposed **Stringer**[7] found that of 13 patients who developed radiological opacities, 5 had abnormal films as early as four hours after operation **Cassels** and **Rapoport**[8] described pulmonary collapse occurring during operation, but these were instances of massive collapse producing immediate signs, and it is probable that the segment or the lobule can collapse without being noticed If in fact the blockage of the bronchus and the absorption of air commonly begin during the operation, the preoperative state and the anæsthetic technique may well be more important than the postoperative treatment A factor worth attention is the effect of anæsthetic mixtures on the rate of air absorption **Dale** and **Rahn**[9] have shown that collapse following bronchial occlusion is accelerated sixtyfold when pure oxygen is breathed in place of air The oxygen content of an anæsthetic mixture might thus determine whether a region of lung distal to a bronchial obstruction was or was not airless when the patient recovered consciousness and started to cough, and complete airlessness must greatly decrease the chance of early dislodgement of the obstruction **Palmer** and **Sellick**'s results suggest a substantial prophylactic advance, and we hope that their valuable analysis will be continued to explore further the corollaries to their encouraging news

Tuberculosis Mortality

Since 1850 the Registrar-General has published year by year the *mortality-rate from tuberculosis* for each sex by age-groups Those figures reveal a [illegible] fall in the mortality in all age-groups, and people agree that this must have been due to improved environmental conditions Apart from this great fall the most interesting feature is the change in age-distribution, and there is now a very [illegible] difference between the sexes for females the death rate is greatest in early adult life, whereas for men it is greatest at about the end of working life

Frost,[1] who has since been followed by others, suggested that this late peak in males could be better understood if it was studied in relation to the earlier higher rates experienced by the same group of men when young adults, an entirely new picture emerged when the rates were studied for "cohorts" instead of calendar years or decennia This view was [illegible] by **Springett**,[2] who showed that, if it were accepted that the mortality curve for females followed an acutely peaked pattern, the postponement of the age of maximum mortality of males, and not of females, could be explained mathematically While [illegible] accepting this reasoning, **McDonald**[3] has suggested that the late peak of mortality in men is associated with environmental conditions at work He bases this view on differences between various occupational, social-class, and geographical groups in England and Wales in the present century, but he does not discuss the possible influences of "migration," not only geographically but also from one occupation to another and from one social class to another Possibly, as **McDonald** concludes, environment at work is partly responsible for the present high mortality in older men but the fact that single women engaged in employment have the same pattern of mortality as married women (though with a rather higher death rate among the employed) does not suggest that this influence can be very strong Furthermore, a century ago, when men worked under far worse conditions and their wives were for the most part at home, the greatest mortality for each sex was in young adult life

Russell[4] has approached these mortality rates in a rather different way He points out that the grouped data used by previous workers, based on 10-year age-groups and decennia, are not an exact guide to the tuberculosis mortality of cohorts He has accordingly estimated the general and the tuberculosis *mortality of twenty-four cohorts of females* born in 3-year periods from 1851–53 to 1920–22 His results confirm the great fall in tuberculosis mortality and the general constancy of the pattern of mortality in cohorts, except when disturbed by such gross influences as the first world war and the influenza epidemic of 1918–19 He confirms also the fact, first recorded by **Picken**,[5] that by the cohort method of analysis, as well as by the conventional calendar-year method, the age of maximum mortality for women is passing to younger age-groups **Russell** states that previous investigations based on the cohort method of study have emphasised the dependence of pulmonary ɔrigin of the inferior mesenteric artery were easily and ɔly displayed by dissection of the pre-aortic peritoneum, ɔathetic fibres, and areolar tissue. The vessel was pulsating ially to within 1 cm. of the bifurcation, below which ; only transmitted thrust was palpable. Beyond, the non iliac arteries were pulseless. The aorta, clamped and d proximally, was next incised vertically for about 1·5 cm. ediately above the bifurcation. Much thrombus was ed from each common iliac artery but was unfortunately preserved. The free retrograde bleeding which followed controlled by digital pressure while the aortic incision being closed with interrupted mattress sutures of fine ded 'Nylon.'

hen the aortic clamps were released, strong pulsation ted in all the visible distal vessels except the left external and femoral arteries. The left femoral artery was there- opened, and a fine soft suction catheter was passed ximally. After this there was a faint left femoral impulse. ·5% solution of papaverine was applied to the exposed sels, as recommended by Kinmonth (1952), and the wounds e closed, leaving fine 'Polythene' tubing down to the ious arteries that had been handled.

s the patient's condition was still fairly satisfactory, the axillary artery was exposed through a curved incision, cave downwards, on the front of the shoulder. The outer t of the clavicular head of the pectoralis major muscle s detached from the clavicle, and the muscle was divided r its brachial attachment. The pectoralis minor was cut ough, the axillary sheath was opened, giving an extensive osure of the artery. The level of cessation of pulsation s in the third part near the crossing of the medial root of median nerve. The nerves were held aside on tapes, and ch thrombus was milked from a 1 cm. vertical incision in non-pulsating segment. The suction catheter was also d. Although free retrograde bleeding took place, no sation returned after the arterial incision was sutured, even er the application of papaverine. The wound was repaired layers round a fine polythene tube.

The operation lasted about two hours.

stoperative Course

The patient was nursed in an oxygen tent overnight. paverine was instilled at intervals through the polythene es. No anticoagulant was given. After causing some xiety for the first few hours the patient improved, and overy was uneventful apart from an episode on the 13th y, when abdominal pain and distension, with some shock peared and lasted about 48 hours. The cause was uncertain it might have been intraperitoneal rupture of a small ri-aortic hæmatoma. No pulse could be felt at any time in y of the affected limbs, but their vitality was never in ubt.

alvotomy

In view of her poor cardiac prognosis and the repeated abolism, Dr. Branford Morgan was of the opinion that lvotomy should be considered. Accordingly the patient as transferred on the 32nd postoperative day to the thoracic it of St. Bartholomew's Hospital at Hill End, where on arch 24, 1952, she underwent mitral valvotomy by Mr. O. S. ubbs. We are indebted to Mr. Tubbs for permission to include tracts from his notes.

"The auricular appendage, which was large and broad, lt quite soft. The base of the appendage was injected with % amethocaine and a Brock clamp applied. The incision the appendage was made from above downwards with the cape of fluid blood. There was no clot inside the appendage ad the endocardium appeared quite smooth. The clamp was omentarily released and no clot was discharged, only fluid lood. A purse-string suture was not employed as the appen- age was so large. A finger was now inserted through the pening. There was no regurgitant stream palpable. An area f calcification in the anteromedial cusp was felt. There was ome difficulty in finding the actual stoma as it was so small. he lateral commissure split easily, but the medial com- nissure could not be made to split. There did not appear to e any calcification at the margins of the opening. After the ateral commissurotomy the stoma would have admitted about ne and a half fingers. The clamp was then reapplied, the tip f the appendage removed for section, and the opening obliter- ated with interrupted mattress sutures and continuous sutures long the border. The chest was closed with an intercostal rain in the posterior axillary line. The patient was returned o the ward and kept in an oxygen tent for the first 24 hours after operation. Her convalescence was smooth and she was discharged from hospital on April 17, 1952.

"*Pathological report.*—The specimen consists of an auricular appendage measuring 3 × 2 × 1 cm. and showing some slight subpericardial hæmorrhage, but otherwise no macroscopic abnormality. Section shows considerable hypertrophy of the muscle-fibres and some organising endocardial thrombus. In one area of the myocardium there is a focus of chronic inflammatory cells, mostly lymphocytes, but there are no specific rheumatic nodular lesions."

Follow-up

The patient was readmitted to the Norfolk and Norwich Hospital on May 2, 1952, looking an entirely different woman. The cyanotic malar flush was gone, as had the dyspnœa, and she could walk up and down stairs with ease. Apart from a flicker in the left radial artery, no pulsation was palpable in any of the affected limbs.

When last seen on Jan. 14, 1953, she had maintained her improvement, and had gained about 7 lb. in weight, felt better than for years, and could do her housework. She could climb stairs without breathlessness and could walk at least a mile at an ordinary pace without fatigue or claudication. She had some pain in the soles of her feet on walking; this took about two hours to pass off, and may have been structural rather than circulatory. The peripheral pulses were still absent, and the feet were cold, with very slight postural blanching.

The patient will remain under observation.

DISCUSSION

Operative Technique

In view of previous papers there is no need to discuss technique in detail. A few points, however, deserve mention—mainly steps which we now consider to have been errors committed in the atmosphere of unusual emergency.

1. It was almost certainly a mistake to expose and clamp the vessels in the groin before opening the abdomen. Our object was to avoid distal migration of portions of detached thrombus, but this danger is likely to be considerably less than that of spasm and intimal bruising caused by the clamping. Temporary occlusion of the common iliac vessels during extraction of the clot has been described by Linton (1945). If any doubt exists about the diagnosis of aortic saddle embolus, it may be correct to explore a femoral vessel first, as in the case described by Fraser and Goldberg (1951).

2. The use of suction tubes, however soft, is inadvisable. According to Linton (1945) gentle handling of tissues and avoidance of intimal injury are cardinal points of technique. External milking followed by momentarily unchecked bleeding should in most cases obviate the need for endarterial manipulations.

3. The arterial incision is probably best placed in the relatively dilated segment just above the point of impaction of the embolus. The contracted segment at and below that point is already sufficiently damaged and narrowed without having to suffer further insult. Failure to observe this point in the case of the axillary artery probably explains the non-return of pulsation in that vessel immediately after the embolectomy.

4. To the general surgeon, his familiarity with the simple transperitoneal approach, and the good exposure it affords, are invaluable when he is called on to tackle this unusual though not unduly difficult emergency (Linton 1945, Ewing 1950).

Effect of Embolectomy

In none of the affected limbs were normal peripheral pulses restored, although, as has been noted, strong pulsation returned in most of the major distal vessels after removal of the aortic clamp. The failure of the vascular tree to return to normal was probably due to a combination of spasm and thrombosis following over-manipulation of the vessels. Even so, it must be emphasised that they were by no means roughly handled; obviously extreme gentleness is required, together with avoidance of endarterial manœuvres.

THE PAINFUL SHOULDER

SHOULDER pain can be a baffling diagnostic problem, as Furlong[1] has lately reminded us The pain may not arise in the shoulder at all it may originate in a neighbouring structure, or it may be referred from a more distant region, such as the neck or thorax True shoulder pain is felt immediately distal to the acromion process, and it often radiates diffusely down the lateral aspect of the upper arm, usually to about the junction of its middle and lower thirds, it seldom extends below the elbow It is almost invariably associated with physical signs in the shoulder, such as local tenderness, swelling, or increase of warmth, impairment of mobility *in one or more directions*, exacerbation of pain on movement, or crepitation Pain of somewhat similar distribution may be caused by lesions involving the brachial plexus or its roots, such as prolapsed cervical disc, osteophytic outgrowths in cervical osteo-arthritis, and tumours in the spine, neck, or thoracic inlet But pain from these causes often radiates throughout the length of the limb to the forearm and hand, it may be associated with neurological signs; and the shoulder itself shows no abnormality It is worth remembering, also, that pain in the shoulder may be a prominent feature of diaphragmatic irritation (for example, from an inflamed gall-bladder) and of angina pectoris Nelson[2] has lately given an admirable account of the differential diagnosis of shoulder pain

Once it is established beyond reasonable doubt that the pain arises in the shoulder-joint, the next step is to consider each of the possible causes Apart from recent injuries, the number of recognised affections of the shoulder is fairly small, and their differentiation is usually not difficult Like other joints, the shoulder is subject to the common forms of inflammatory arthritis (acute suppurative, rheumatoid, tuberculous) Unlike other large joints it is only rarely affected by osteo arthritis (presumably because it is seldom subjected to thrust-stresses) On the other hand it is commonly the site of affections that have no true counterparts in other joints The chief of these are the supraspinatus, or painful-arc, syndrome, rupture of the musculo-tendinous cuff (often termed, less accurately, the "rotator" cuff), and "frozen" shoulder

The *supraspinatus syndrome* is common, clinically distinctive, and satisfactorily explained by the structural relationships in the upper part of the shoulder During the mid-phase of shoulder abduction the non-articular part of the upper end of the humerus passes close beneath the coraco acromial arch, the clearance just suffices to accommodate the structures that lie between them—the supraspinatus and adjacent tendons blending with the capsule, and the flimsy walls of the subacromial bursa Consequently if any tissue in this area is swollen and tender it will be nipped between humerus and coraco-acromial arch during the critical mid-phase of abduction, thereby causing the painful arc of movement characterising this syndrome Five distinct lesions may be primarily responsible minor rupture of supraspinatus tendon fibres, supraspinatus tendonitis (a localised degenerative lesion), calcified deposit in the supraspinatus tendon, subacromial bursitis, and a minimally displaced avulsion fracture of the greater tuberosity

Rupture of the musculo tendinous cuff raises problems of applied anatomy, of diagnosis, and of treatment The classical picture of a major tear of the supraspinatus and adjacent tendons is well known there is inability to abduct the arm through the early part of its range, though if the limb is abducted passively the position can often be sustained against gravity without assistance But theoretically the deltoid muscle should be sufficiently powerful to abduct the arm against gravity without the aid of the supraspinatus, and it is not fully why it usually cannot do so The most explanation is that the *supraspinatus* normally the articular surface of the humeral head closely to the glenoid fossa, thereby ensuring a stable of movement Without supraspinatus action the head tends to be pulled upwards away from the fossa by the deltoid, and the stability of the fulcrum is lost Early diagnosis of major tears of the cuff is difficult because certain other painful of the shoulder *can cause* temporarily a similar loss abduction, through reflex inhibition Yet prompt nosis is important because operative repair is and more likely to be effective in the early stages Ell has recently called attention to two aids to diagnosis—the procaine-injection test and contrast arthrography By injection of procaine into the area of tenderness pain is temporarily abolished if the patient is enabled *to abduct the arm actively against* gravity a major tear is unlikely Arthrography will demonstrate a communication between the shoulder joint and the subacromial bursa if a communication is present the tendinous cuff must be torn These tests can be of real practical value, but without special skill and experience in their performance and interpretation the results may be equivocal Effective treatment of these major tears of the *cuff presents further difficulties In general* the results of operative repair are poor, it seems that simple suture will often be unsuccessful because the tendon is usually degenerate Possibly attempts by other means to provide a stable fulcrum, whereby the deltoid could take over the sole control of abduction, might be more successful one possibility would be to establish a new joint surface between the upper end of *the humerus and the under surface* of the acromion

"*Frozen*" *shoulder* presents some of the most baffling of all shoulder problems. For no clear reason, and typically without preceding injury, the shoulder becomes painful and stiff There is a proportionate limitation of all movements, which are often reduced to as little as 20–30% of the normal range Yet there is no clinical evidence of an inflammatory arthritis, and there are no radiographic changes The underlying lesion is uncertain Reports of the appearance of the joint in the relatively few cases where operation has been undertaken are conflicting Thus Codman[4] found congestion over the supraspinatus tendon in the floor of the subacromial bursa Lippmann[5] found adhesive tenosynovitis of the long tendon of the biceps, and believed this to be a causative factor Simmonds[6] reported chronic inflammatory changes in the musculo-tendinous cuff, and to a slighter extent in the whole of the capsule, but stated that the biceps tendon was *unaffected* He believed that "frozen" shoulder could be correlated with degenerative lesions of the cuff Others, however, regard it as an independent clinical entity Arthrographic studies have shown defective filling and reduced capacity of the synovial cavity, but the significance of this finding is not yet clear, most observers agree that the interior of the joint itself appears normal at operation[7] In the face of this conflicting evidence it must be admitted that we have no certain knowledge either of the cause or of the pathology of "frozen" shoulder

Nor is the relation of the *ordinary* "*frozen*" shoulder to the "shoulder-hand" syndrome clear In the latter condition the development of a stiff and painful shoulder is followed after an interval by similar *stiffening* of the hand and fingers, which assume a position of flexion and become progressively more useless, with cold glossy

—Protrusion of 1st metatarsal in 249 radiographs of feet of normal people.

head of the second [metatarsal] to be the most nced member of the series.”

view of these conflicting statements the following rvations, made on cadavers during an investigation ie human ankle-joint, may be of interest, especially here does not seem to have been any similar stical inquiry into this subject.

OBSERVATIONS

the cadaver 133 feet were measured by a standard edure. The toes were amputated at the metatarso-langeal joints, and the perpendicular distance was sured from the head of the first metatarsal to a line wn through the tip of the second metatarsal at right les to its long axis. This assessment of the relative minence of the two bones accords with Morton's hod, which, although open to criticism (Harris and th 1949, Hardy and Clapham 1951), is the one most ely used and is moreover the method adopted by protagonists in this controversy.

here were two possible sources of error in the series: the subjects were all elderly, many showing minor t disorders, and (2) the muscles had been dissected y and consequently a partial collapse of the medial gitudinal arch was sometimes found. To estimate the ct of muscle stripping, 18 feet were radiographed ore dissection. The measurements obtained from the iographs did not differ materially from those made m the specimens after dissection. To assess whether had any effect, 249 radiographs of normal people, st of whom were between the ages of 16 and 20, were asured by Morton's method. These radiographs were ained by a standard technique and have been fully lysed by Hardy and Clapham (1951). Their method recording metatarsal protrusion differed from that pted in the present investigation, however.

he findings in the two series are illustrated by histo-ms. The first metatarsal was less prominent than the ond in 53% of dissected feet (fig. 1), and in 47% of radiographic series (fig. 2). Statistical analysis shows significant difference between the two sets of data. therefore seems justifiable to combine the two sets figures and to state that the first metatarsal is less ominent than the second in about half the total of 382 t.

The relative protrusion of the first 2 metatarsal heads not only of academic interest, for Morton's views on mechanics of human gait are based on the supposition at the two bones normally extend to the same transverse line. Before any foot disorder can legitimately be ascribed to “shortness” of the first metatarsal, the normal anatomical variation must be recognised. For example, in the 15 feet showing march fractures recorded by Flavell (1943) the variation in metatarsal protrusion does not differ significantly from that found in the present series of normal feet. In a large series of fractures of the second metatarsal bone analysed by Leveton (1945) this bone protruded beyond the first in 49 out of 87 cases. Leveton tentatively concluded that “if the second metatarsal is longer and protrudes beyond the other segments it is apt to be the site of fracture,” but this statement is valid only if there is a higher incidence of protrusion of the second metatarsal in the pathological series than in a normal one. In fact, statistical analysis indicates no significant difference between Leveton's figures and the normal incidence described above. At present there is insufficient evidence to incriminate protrusion of the second metatarsal as the important predisposing factor in the ætiology of march fracture.

SUMMARY

133 dissecting-room feet, and radiographs of 249 normal people, have been measured by Morton's technique. In about half of them the first metatarsal was less prominent than the second. This normal variation should be borne in mind when considering the ætiology of march fracture.

We are indebted to Prof. H. A. Harris, Prof. M. F. Lucas Keene, and Prof. J. Z. Young for allowing us to study material in their departments; to Dr. R. H. Hardy for his generosity in placing his radiographs at our disposal; and to Dr. D. A. Sholl for statistical advice.

INFLUENZA IN EARLY PREGNANCY

EFFECTS ON THE FŒTUS

W. A. B. CAMPBELL
M.D. Belf., M.R.C.P.E., D.C.H.
ASSISTANT PÆDIATRICIAN, ROYAL MATERNITY HOSPITAL, BELFAST

A FAIRLY severe epidemic of influenza (A-prime) in Northern Ireland in December and January, 1950–51, afforded an opportunity to discover whether influenza in the early months of pregnancy produces fœtal abnormalities, in a manner similar to rubella.

A meeting of obstetricians, pædiatricians, and public-health medical officers was held; and, since retrospective inquiry, after delivery, into the illnesses of early pregnancy is liable to yield inaccurate information, this meeting decided that the inquiry should be prospective. A small committee * drew up the following plans:

The survey was to include, as far as possible, all mothers attending the antenatal clinics of the Belfast City Hospital, the Royal Maternity Hospital, Belfast, and the maternity and child-welfare service of Belfast Corporation, the first day of whose last menstrual period was between Sept. 1, 1950, and Jan. 31, 1951.

Each of these mothers would be asked whether she had influenza, defined as “a febrile illness with a sharp onset, characterised by pains in the legs, back, or head, and sufficiently severe to require that the patient went to of protein Dock's[4] experiments with Winton's technique of perfusion of kidneys with ice cold serum suggest that the glomerular capillaries resemble those of the choroid plexus in filtering a fluid containing some 15–20 mg of protein per 100 ml This modest leakage of protein would lead to heavy proteinuria but for tubular reabsorption The results of analysis of fluid obtained by glomerular puncture in animals have been equivocal on account of technical difficulties, but on the whole they point to glomerular filtration of protein Injection of proteins foreign to plasma, such as hæmoglobin, leads to their appearance in the urine only after a plasma "threshold" level has been reached—a fact best explained on the supposition that at such a plasma level the tubular reabsorptive capacity has been saturated Protein reabsorption appears to occur in the proximal convoluted tubule, and may give rise to hyaline droplet formation (athrocytosis) in the tubular epithelium when the reabsorptive mechanism is being overloaded

---

* The committee consisted of Prof. A. C. STEVENSON, Dr. H. A. WARNOCK, Mr. W. S. CAMPBELL, F.R.C.S., and Mr. G. B. GIBSON, F.R.C.S.

One innocent type of proteinuria is that related to exercise Javitt and Miller[5] attribute this to increased glomerular leakage of protein which, they say, is due to the acidæmia of exercise that is supposed to have a softening effect on the intercellular cement substance of the glomerular capillaries, a potentiating factor may be anoxia from reduced renal blood-flow The degree of proteinuria is not related to the pH of the urine, which does not affect tubular reabsorption of protein This is not surprising, since the urine is acidified in the distal convoluted tubule In 3 normal persons studied by Javitt and Miller, albumin/globulin ratios of exercise proteinuria were less than unity Obviously, molecular weight is not the only factor in determining passage through the capillary membrane, and thought must be given to such other factors as the relative amounts of each class of protein in the plasma, molecular structure, and molecular electrical charge

Other types of innocent proteinuria, and also the proteinuria of organic renal disease, require further study along such lines as those followed by Javitt and Miller. Investigators should beware of fallacies, one of which has lately been uncovered by Doxiadis and his colleagues[6] These workers have proved that physiological proteinuria does not occur in the newborn infant, belief that it did had been based on false results from the highly concentrated urine, containing large amounts of urates, that may be passed in the first week of life

ALOPECIA AREATA

THERE has been remarkably little progress in our fundamental knowledge of the causes of loss of hair since the description in *Leviticus* of the differences between leprotic and non-leprotic forms of alopecia We recognise an androgenic alopecia in both males and females and we recognise loss of hair from various scarring diseases affecting the scalp But what of alopecia areata? Is it caused by an infection, is it a "trophoneurosis," or is it a symbolic expression of inadequacy, usually sex-based?

Anderson[7] in a study of 114 patients with alopecia areata found that there had been an emotional shock before the onset in 23%, and various degrees and forms of mental disturbance in another 22% A further 28% had some kind of infection, general and local, or vague ill health before their hair began to fall, but the remaining 27% were apparently in perfect physical and mental health The condition often affects children, and Brown[8] found that in 300 patients 57% of first attacks occurred under the age of 21, and only 9% over 40 The focal-infection and eye strain theories have largely been counted, and opinions now seem divided between explanation of emotional symbolism and that a hypothetical virus or toxin which causes a t neurosis, but no single theory seems to fit all cases

Ignorance of the cause leaves treatment in an state of uncertainty The rubefacient effect of u violet irradiation applied by a physiotherapist is g believed to be more effective than a similar result p duced by the patient's own efforts with "[illegible] If this is true it suggests that the kindly presence of t physiotherapist has more influence on hair growth th the remote figure of the doctor symbolised by the b on the mantelshelf Feeny[9] reported that local app tions of thorium-X were effective, but other wor have found that, while it succeeds in some pat others remain unchanged or even become worse Wh different people obtain such different results, the influ of enthusiasm and confidence must be weighed on t one hand against casualness and scepticism on the oth Many endocrine substances have been used with success Walker and Rothman[10] examined 230 patie with alopecia areata, and came to the conclusion that i the overwhelming majority there was no evidence o endocrine abnormality to be found from phy examination or laboratory tests They neverthe thought that endocrine factors might play a small pa because alopecia areata is often more severe wh begins before puberty, because regrowth may o during pregnancy[11 12], and because some example alopecia areata begin at the same time as thyrotoxic They had no success with large doses of oestro progesterone, lactogenic hormone, and deoxycort

Wilson[13] has now described regrowth of hair in 1 patient with alopecia areata and in 3 with alopecia universalis 8–10 days after the beginning of treatm with adrenocorticotropic hormone (A C T H) He co cluded that this effect might be due to the influence o A C T H on inflammatory exudates, to inhibition of t allergen, to increased local blood-supply, or to a specific adrenal hair-stimulating hormone Dillaha a Rothman[14] have described partial regrowth in 16 out o 22 patients treated with cortisone (100–150 mg daily In 14 the regrowth occurred 3–4 weeks after the star of treatment It was usually only patchy but sometim the cosmetic result was satisfactory The axillæ and th pubis were most resistant to the effects of cortisone I 3 patients new patches of baldness developed during th treatment The average duration of alopecia in the fail cases was 11 7 years (with a range of 4 to 20 year compared with 4 7 years in the successful cases (3 mont to 14 years) Alopecia starting at puberty seemed to have a bad prognosis One patient also had nail changes and these improved as the hair regrew, but both hair and nails relapsed soon after treatment was stopped Similarly, Wainger[15] has illustrated successive improvements and relapses in a patient with alopecia universalis during and after treatment with A C T H and cortisone Dillaha and Rothman conclude that cortisone may act by bringing about some change in the local chemical *milieu* which perhaps influences sebaceous gland function or keratinisation However, they emphasise strongly that they do not recommend this form of treatment for general use

Regrowth of hair during treatment with A C T H or cortisone seems to be a direct result of the treatment and not of suggestion, for it regularly begins 3 to 4 weeks

Medical Societies

MANCHESTER MEDICAL SOCIETY

Cerebral Abscess

a meeting of the pathology section of Manchester al Society on Nov. 12, Dr. G. K. TUTTON said that aprovement in the results of surgical treatment racerebral abscesses was due to the control of ial infection by antibiotics and the avoidance of traumatising drainage procedures. A 20-year y of the cases seen in the Manchester University surgical unit showed an increasing number of cases diminished death-rate since the use of penicillin 15. The mortality for treated cases of all types up years ago was 60%; for 68 cases since then it had to 29%, or 13% (in 54 cases) excluding 14 untreated its in whom the condition was undiagnosed during

cteriological examination was of paramount impor-, since this indicated the correct choice of antibiotic. liagnosis and localisation great use had been made ctro-encephalography, which showed a characteristic delta activity with a delta focus very close to all lying supratentorial abscesses. Air ventriculo-ty was rarely used, but occasionally carotid ography was of value.

these means abscesses could be so precisely localised aspiration was feasible. Excision, either early or was practised only in certain cases where aspiration ailed.

scesses were due either to direct or to vascular d, either from extrathoracic sources or from sup-tive chest lesions. Of 8 patients with cerebral sses from extrathoracic sources none had died; of 10 patients with abscesses from thoracic lesions d died. In the latter group the diagnosis was ed less quickly, and here antibiotics were the most rtant therapeutic factor. 3 patients with multiple ral abscesses had had successful pulmonary resec-. Of 23 patients with frontal or occipital lobe esses, mostly from direct spread of infection, none died. Of 12 patients with temporal otogenic abscesses d died; and of 7 with cerebellar otogenic abscesses d died. Of 12 patients with abscesses, vascular in n, in the parietal lobe 3 had died.

the last 37 cases of cerebral abscess, 21 had penicillin-tive organisms and were sterile after two aspirations instillation of penicillin; 2 needed more than three ations, and 2 never became sterile so that excision necessary. The remaining 16 cases, which had cillin-resistant organisms, were otogenic. In peni-t-resistant cases there was no really suitable anti-c for local instillation; for streptomycin has a limited on, and chloramphenicol and aureomycin were rela-y insoluble. Polymyxin has been tried in 1 case only. cases due to resistant organisms local application of a 000 solution of hydrarg. perchlor. had proved useful.

r. LEWIS PARKER referred to 68 cases of brain ess, 60 of which had been examined bacteriologically. n the initial specimens of pus 61 strains, from 10 ies or groups of associated species, of bacteria were ted. The commonest organisms were *Staphylococcus genes* (15), *Proteus vulgaris* (11), and non-hæmolytic ptococci (9). This wide range of bacteria underlined need for careful bacteriological examination.

r. Parker outlined a comprehensive technique of mination, including stained film of the pus; blood-r plate culture incubated under aerobic, micro-philic, and anaerobic conditions; and broth culture Brewer's thioglycollate medium, glucose broth, and tley's broth.

he bacteria found in an abscess were related to the terial flora at the primary source of infection. Thus abscesses in the temporal lobes or cerebellum, due to direct spread from the ear and associated structures, were mainly due to gram-negative bacilli, *Proteus vulgaris* being the commonest; anaerobic organisms had been found on several occasions. Abscesses in the frontal lobe following direct spread from the frontal sinuses were due to normal inhabitants of the upper respiratory tract, mainly gram-positive cocci.

Abscesses arising through direct-spread from osteomyelitis of the skull or through fracture of the skull were usually due to *Staph. pyogenes*. Hæmatogenous spread from the chest was due mainly to non-hæmolytic streptococci and the bacteroides group of organisms; in 5 of these 12 cases no organisms had been isolated from the pus. Other workers had also experienced this high proportion of negative findings.

The sensitivity of the organisms to antibiotics was determined by the dried-disc and by the serial-dilution techniques. Local administration of the appropriate antibiotic was necessary when the abscess was encapsulated. Penicillin and streptomycin were given most commonly. In many cases the abscess was rapidly sterilised, but in some the organism proved resistant to these antibiotics, and in 4 of such cases chloramphenicol or aureomycin had been used locally with good results. The combined administration of two or more antibiotics had been considered in recent cases, but this had not been found necessary in any of the cases investigated.

Reviews of Books

The Science and Art of Joint Manipulation

Vol. 2. *The Spinal Column.* JAMES MENNELL, M.A., M.D. Camb., consulting physician in physical medicine, St. Thomas's Hospital. London: J. & A. Churchill. 1952. Pp. 264., 42*s*.

PERHAPS science and art should be transposed in the title of this book, which complements Dr. Mennell's earlier volume on the extremities. On such topics as the "binding" of joints and sacro-iliac strain he sets out at length individual views which may not be universally accepted. And yet, as in other fields, such is the importance of close attention to the patient, in sum and parts, that the application of a particular skill may yield empirically the most satisfactory results. Of the practical value of Dr. Mennell's methods there can be no shadow of doubt, even if some of his therapeutic arrows succeed by reaching quite other than their ostensible targets. And who will not applaud the comment that "It is not a great thing to ask that, when symptoms do not conform to routine diagnosis or do not respond to treatment, the joints corresponding to the region of the symptoms should be examined"? Errors in diagnosis will persist until the technique of joint examination takes its proper place in medical and orthopædic training. Meanwhile, we can refer to Mennell.

✓Biochemistry and Human Metabolism

B. S. WALKER, M.D., PH.D., professor of biochemistry, Boston University School of Medicine; W. C. BOYD, PH.D., professor of immunochemistry, Boston University School of Medicine; I. ASIMOV, PH.D., assistant professor of biochemistry, Boston University School of Medicine. Baltimore: Williams & Wilkins. London: Baillière, Tindall, & Cox. 1952. Pp. 784. 68*s*. 6*d*.

THIS outstanding book contrives to present modern biochemistry, without undue simplification, in the main fields which touch on clinical medicine, and it also tells the biochemist about the medical significance of his subject. These things it does in a style so free that it is a pleasure to read. The organisation of the contents is unusual for a textbook of biochemistry: it deals first with structure, pride of place being rightly given to proteins, and then with control by enzymes and hormones, with growth (with consideration of nucleoproteins, cancer, and heredity), with metabolism, including nutrition, digestion, respiration, excretion, and electrolytes, and finally with the pathology of vitamin

SOME PRACTICAL CONSIDERATIONS IN THE CARE OF THE OLD*

NANETTE H NISBET
M D Glasg
SOMETIME CHRISTINA HANSEN RESEARCH FELLOW IN THE UNIVERSITY OF GLASGOW

> "You are old, Father William," the young man said,
> "And your hair has become very white,
> And yet you refuse to remain in your bed
> Do you think, *at your age*, it is right ?"

THE attitude of doctors and administrators towards sick and infirm old people has been discussed many times in recent years Reports from various parts of the country reveal what can only be described as a state of widespread apathy for the plight of old people in need of medical care These reports emphasise the need to provide opportunities for medical students and doctors to work for a time, at any rate, among old people Not the least important advantage of this kind of experience is that the doctor becomes aware of the far-reaching effects of the social policy of a community on the standards of medical practice In my own experience of institutions for old people I have heard the remarks that indicate the unimaginative outlook Here are some of them

"These patients are sent here to die, nothing can be done for them If it could, it would have been done in the hospitals they came from"

"Nothing must be done for them, for the nursing staff are employed on that understanding, and they will refuse to work here if any treatment is begun"

'If the lay administrators could sign death certificates there would be no need for a doctor"

"If you make this place too attractive, too many will want to come in"

"There is no use in re educating the patients to walk if they cannot be discharged, for no hospital beds will be released thereby"

'Anyhow they have been in bed too long, and are all confused and senile"

"The food cannot be as bad as that, or someone would have complained before"

"Clothes cannot be supplied to hospital patients, anyone who is fit to be out of bed is fit for Part III accommodation."

A Survey in a Hospital

A survey at a former poor-law institution was made between September, 1949, and February, 1950, and concurrently reforms were proposed At the time of the survey there were 622 patients in the hospital, 207 women and 415 men They could be grouped in the following categories

(*a*) Those who could walk but were not fit to live alone or in part III accommodation 79 women (38% of the 207 women) and 145 men (35% of the 415 men)
(*b*) Those who needed constant help, or re education in walking 60 women (29%) and 176 men (42%)
(*c*) Those who were unlikely to walk again and needed nursing care 68 women (33%) and 94 men (23%)

Only 45% of the men and 30% of the women had been in the hospital for less than a year, that is, the majority had been an unconscionable time a-dying How much longer were they likely to live ? The fact that elderly people are likely to die within the next ten, twenty, or thirty years seems to be no good reason for leaving them untreated—unless we wish to follow Osler's jocular suggestion that everyone should be quietly disposed of with chloroform on reaching the age of 60

In view of the régime to which the nurses had become accustomed, it was to be expected that they would at first be sceptical about proposed reforms They echoed —not smugly but regretfully—the prevailing note, saying "These patients have been in bed too long for anything to be done now" They feared to be held responsible "if anything happened" to a patient when up (anything that happened as a result of lying in bed was a venial offence), and regarded "letting a patient fall" as a nursing crime to be avoided at all costs To some people it is axiomatic that falls are always the result of a nurse's carelessness, but in point of fact they can happen even when a nurse is standing close to the patient's chair The nurses had also noticed the transient spells of unconsciousness in the elderly which are discussed below, and were reluctant to allow patients out of bed except on the most definite and specific instructions from the doctor.

In that they were perfectly right There are some who regard rehabilitation as a nursing affair "Tell the nurses to get them up, that's all." But it is not the business of a nurse to decide that a patient is to get up, or how he should be got up, and for how long If an elderly patient who has been in bed for years is suddenly dragged out and stood on his feet, he may become unconscious, or feel so ill that he subsides on the floor and makes no effort at all

A doctor, about to tackle Mrs McA, was told that she had been up once before and had been most uncoöperative: she had been lifted out of bed and helped to her feet, and—according to the ward sister—she just sat on the floor and screamed According to the patient she felt "dreadful" and thought she was going to die This patient had been years in bed, and her hæmoglobin was only 6 3 g per 1

The nurses, however, as soon as they saw what could be done, and realised that it was for the good of the patients, offered no opposition to the new plans, and their attitudes ranged from interested toleration to extreme enthusiasm Even the most conservative sisters were soon uttering the accepted dogmas of geriatrics The sister in whose ward rehabilitation was first begun possessed a fine pioneering spirit, and the policy "let bad alone lest worse should befall" was obviously abhorrent to her nature In spite of the most distressing criticisms levelled at her from some quarters she never wavered in her enthusiasm and loyalty The nursing staff was far too small for a geriatric unit, and unsuitably distributed, the nurses were much hampered by domestic duties of polishing and dusting, and the lack of some of the usual nursing aids, such as trolleys, and they had—until the patients were regrouped in October 1950—very difficult heterogeneous wards, with a further admixture, in winter, of acutely ill adults and infants But by their brisk and intelligent cooperation they made possible far greater progress than would ever have been accomplished by twice the number of apathetic nurses

Given the requisite enthusiasm, many of the initial steps in rehabilitation can be taken without waiting for elaborate equipment or physiotherapists—this hospital of course had neither The absence of certain basic necessities, however, was an almost overwhelming drawback The shortage of clothes, armchairs (there were neither padded chairs nor cushions), and outdoor shoes (which are much better than slippers for those relearning to walk) greatly retarded progress The cold draughty wards, the slippery hospital floors, and the lack of hand-rails and wheel-chairs made it unnecessarily difficult to induce the patients to make a real effort When rehabilitation first began there were not even enough dressing gowns to go round, and the patients had to be got up in relays When a dressing gown went to the laundry several patients had to be kept in bed until it returned Those who were up had to take turns of the few armchairs Although there had been some improvement since September, 1949, when the general survey was begun, in the first half of 1950 there were only [illegible] armchairs and 61 frocks available for 108 female "up

THE LANCET

LONDON: SATURDAY, JAN. 24, 1953

Experimental Teratogenesis

OUR attitude towards congenital malformations d fœtal death is now changing greatly. There was a ne when tragedies of this kind were regarded as a tribution for some maternal sin of omission or comission. MENDEL's work, however, and the birth of e science of genetics, made it possible to regard onsters as a matter which was finally decided at the oment when conception took place. From this ate of mental resignation we were aroused in 1941, hen the clinical work of GREGG[1] on the association maternal rubella with fœtal cataract suggested that en brief interference with the environment of the etus during its development sometimes produces ngenital abnormalities. Since then other clinical idence has accumulated.

For the last fifty years the experimental embryogists, led by SPEMANN, have been producing monsters aquatic creatures by interfering with the embryo. he number of agents used successfully for this urpose is very large, and it appears that the precise ature of the agent may be less important than the iming and the magnitude of the interference. For bvious reasons such methods could not all be applied o the relatively inaccessible mammalian embryo; nd a new technique had to be adopted by which the aternal-fœtal system as a whole was exposed to the gent under investigation, the mother conveying this gent indirectly to the developing tissues. Thus ALE[2] was led to suggest that lack of vitamin A in he maternal diet could cause anophthalmos in pigs nd since then other workers have investigated in odents the teratogenic effects of other vitamin eficiencies and of many physical and chemical agents. mong these agents was anoxia, which is easily tandardised and readily applied; and we owe to NGALLS and his co-workers at Harvard[3] the idea of using the mouse for a systematic study of the results of maternal anoxia at different stages of pregnancy.

Mice at a known stage of pregnancy were exposed to a low atmospheric pressure for a single period of five hours; and the litter was subsequently delivered by laparotomy on the nineteenth day of pregnancy. Control pregnant mice maintained at normal atmospheric pressure were treated in the same way. The fœtal death-rate was significantly greater in the experimental group than in the controls; and among the living embryos in the test series there occurred gross malformations, such as septal cardiac defects, irregularities and fusions of ribs and vertebræ, cleft-palate, and anencephaly. In the controls some of these defects were not observed at all, and the incidence of others was negligible. INGALLS and his colleagues believe that the genetic strain of the mice used may partly determine the site and incidence of the defects; but the degree and timing of the anoxia are also important. Mice exposed to a pressure equivalent to a height of 27,000 feet produced more deformed fœtuses than those exposed to a "height" of 25,000 feet, and the deformities were more severe. Again, exposure during the ninth or tenth days of gestation caused malformations of the ribs and vertebral column; but the same exposure at other times produced quite different forms of damage. They suggest that anoxia affects the tissues which at the time of exposure are rapidly differentiating and therefore have a high oxygen demand.

This study is undoubtedly of clinical interest. Brief acute anoxia can produce fœtal deformities in mice. What, then, of anoxia in man? There is some fragmentary evidence, summarised by INGALLS and his associates, that among peoples living at high altitudes the incidence of congenital deformities and the fœtal death-rate may be higher than at sea-level. It might also prove valuable to pursue the possibility (already raised by a case-report by OLIM and TURNER[4]) of an association between congenital defects and maternal anoxia from cardiac conditions or acute anæmia. Much more important, however, is the broad concept that lies behind this work. Anoxia is merely a convenient example of what is fashionably called a "stressing agent"; and if, as seems possible, congenital defects can be produced, even though perhaps only in susceptible people, by non-specific maternal stress, a whole new field will at once be opened up for quantitative as well as qualitative study. The problem is a long-term one, especially since experimental results must be correlated with parallel clinical research; but in the end it may be, as INGALLS and his colleagues suggest, "that intelligently conceived measures to protect the fragile embryo or the vulnerable fœtus will ultimately be devised." It is a sound objective.

The Postoperative Chest

POSTOPERATIVE chest troubles are still common enough to disturb the abdominal surgeon. It is true that many of the incidents are trivial and appear as a mere exacerbation of pre-existing bronchitis; but at the best they add to the patients' discomforts, and even minor episodes may carry a risk of bronchiectasis or other permanent damage.[5] The usual lesion is an infected area of collapse—commonly of a patchy lobular, or segmental, distribution, but sometimes involving a lobe or a whole lung. Prophylactic breathing exercises and penicillin are still widely used, though PALMER and SELLICK[6] could find nothing to recommend them. However, in an article in this issue they describe very different experiences with inhalations of a bronchodilator, used in combination

[6] Palmer, K. N. V., Sellick, B. A. *Lancet*, 1952, i, 345.

Walshe (1946) states that the term "vasovagal" was originally coined by Gowers for attacks (described to him by patients) of a growing sense of precordial and *abdominal discomfort and a feeling of impending death*, the extremities and the face grow pale but consciousness is not lost Nothing is known of the heart action in these attacks which develop slowly and pass off slowly, lasting as long as half an hour Pickering (1951) writes that he finds it particularly difficult to accept the idea of cerebral arterial spasm to explain attacks of transient paralysis in patients with essential hypertension There is usually no precipitating factor and *consciousness is not lost* He has seen similar attacks in patients with mitral stenosis and auricular fibrillation, which may be attributed to blockage by an embolus, therefore similar attacks in hypertension may also be due to organic occlusion of a cerebral artery—by thrombosis, or hæmorrhage into the wall, or by sudden expansion of the wall (arteriolar necrosis) Further investigation of the "wee turn" is obviously necessary

Falls in the Elderly

There are many causes of falls in the elderly and the results of even a very minor fall can be serious Some complain that they could "trip over a pin" this may be due to incoordination, weakness, or shuffling gait, but the inability to recover balance quickly—as a younger person would—is the real disability Slippery or uneven ground and poor vision may also add to their troubles, so that they feel very unsure of themselves, and the exclamations of well-wishers to "watch" and "take care" only add to their anxiety Quite often a *patient, when questioned after a fall, will admit to* having felt off colour and shivery all day, and is found to have pneumonia—the cause, not the result, of the fall Some find that their unsteadiness increases in confined spaces, as in parkinsonism, or after prolonged sitting, or in unfamiliar surroundings Sheldon (1948) found vertigo an important and distressing symptom, it was present in one form or another in 51 6% of his cases He suggests as causes, changes in blood-pressure, and diseases of the ear, but considers that "senile degeneration of the labyrinth" is most likely especially as the incidence increases with age This vertigo may be severe enough to make standing impossible, and is often induced by looking up This is also noted by Critchley (1948) Alcohol and sedatives naturally increase any *tendency to unsteadiness Platt (1950)* emphasises that dizziness is not invariably present in hypertension, it is not rotatory as in labyrinthine upset, but is more a light-headedness after stooping Sudden extreme weakness, with or without unconsciousness, usually occurs at rest but may result in the patient's falling off his chair Similar attacks are common where the stool type of commode is used, the fall may be due to loss of balance, or to a sudden cerebral anæmia caused by straining or sudden defæcation Another cause of falling is sudden weakness of the legs, similar to that at the onset of cerebral thrombosis but affecting the legs only and of very brief duration Though remaining fully conscious, the patient may be completely helpless and quite unable to rise Sheldon suggests that the whole *central* mechanism subserving postural tone is liable to sudden failure More definite causes of falling are the sudden onset of cerebral hæmorrhage or thrombosis with immediate onset of paralysis and in some, a complete loss of consciousness A substantial proportion of such attacks pass off in a few days

Of the patients at the hospital I have been describing 5% complained of dizziness or unsteadiness Sheldon found a liability to fall in a third of his cases, and that it increased with age and was commoner in women, the younger age groups complained of a feeling that they might fall

Often a fall, especially in the street, results in a to hospital, this was the original reason for admission 8% of the females and 6% of the males in the hosp at the time of my survey McEwan and Laverty (19 found falls to be the cause of admission in 6% of the cases and a liability to falls in a further 4% Only a of the patients admitted after a fall were found to ha some definite lesion, such as hemiplegia or fractur femur, but all except a very few were appar destined to languish in bed for the rest of their li Certainly, as Sheldon remarks, a fall may precede general break-up But that is a terminal condition, a it is only too common to find a patient who fell ten yea ago, and who has no demonstrable lesion as the cause result of the fall, still confined to his bed

When rehabilitation began a few patients objected getting up lest they might fall, but it was usu found that relatives or nurses had advised staying in Such excessive caution is partly due to humane motiv but partly to that fear of responsibility which been alluded to before True even a simple fall may disastrous for the elderly patient, but it would be even worse disaster if fear of falling were regar as a good reason for keeping so many people in bed

Treatment of Incontinence

It is easier to prevent incontinence than to cure once it has become habitual A patient who finds h incontinence accepted by the nurses comes to consi it inevitable, and ceases to try to prevent it For th *reason a patient should never be told that he is necessaril* incontinent because he has had a stroke Tho Thomson (1949) asserts that there is general agreem *that incontinence cannot be avoided by bedpan roun* at frequent intervals, there are some patients who remain continent if given a bedpan at frequent regu intervals or immediately on asking If the patient incontinent at night, he should be wakened some tim before the incontinence has occurred and encourage to pass urine It is always worth while to try th *effect of reducing the fluid intake in the later part of th* day, though not always effective, this expedient mak all the difference in some cases Some patients wou benefit if a bedpan were offered not only after meals bu before meals An adequate number of bedpans an urinals is essential, for some cannot pass urine to orde Male patients can often be kept continent if there is urinal within easy reach and if care is taken to emp it frequently The urinal holder described by Ingha (1951) should be more widely used Patients of eith sex may find the bedside commode easier to use tha the bedpan, even if they have to be lifted out of be *It is recognised that the bedpan is difficult to use in be* and it has been *proved* that patients expend mo energy *on* it than on the bedside commode (Benton et a *1950) Malcolm Donaldson (1948) noting that his ow* device of a bedpan below the bed with a special mattre and drawsheet is considered too elaborate, feels that th bedpan should be redesigned to make it deeper and mo stable

A rubber bedpan seems ideal, but is not popular wi nurses because of the difficulty of cleaning rubber and i perishable qualities The use of a bedside commode condemned by some as being æsthetically unpleasan But where there are feeble patients with frequenc and precipitancy, the presence at the bedside of a com mode, which they can manage to use unaided—withou having to attract the attention of a nurse or mak their way to the toilet—prevents much incontinenc especially at night, in understaffed wards, and al allows the patients to preserve some feeling of ind pendence For those who are feeble and slow at walkin the thought of having to walk some distance to the toil perhaps along a cold passage or up or downstairs, mak erculosis mortality in adult life on that experienced the same group in *childhood*. This is not entirely ect: the most distinct relation shown by vious workers is between the tuberculosis mortality young adult life (15–24 years) and that of later age- ups; in fact the childhood, and especially the ler-5-year, rates do not fit at all well with the iort pattern. **Russell** has calculated the correla- ns between four variables: childhood environment, ldhood tuberculosis infection, adult environment, d adult tuberculosis mortality. The correlations tween these variables would be of great importance the indices taken as representing them were fully ceptable. **Russell**, however, measures adult environ- ent by the adult mortality from all causes other than berculosis. **Kermack** et al.[6] have shown that ortality from all causes tends to be determined by e childhood experience of the cohort. Hence the gh degree of correlation shown by **Russell** between pulmonary tuberculosis mortality and general mortality in the same 5-year age-group cannot be ascribed solely to the dependence of tuberculosis mortality on contemporary environmental conditions. **Russell** confirms **Hill**'s[7] earlier finding that there is no statistical evidence from the national figures that the decreasing tuberculosis mortality under 15 years of age is associated with any rise in tuberculosis mortality in older age-groups.

Both **Russell** and **McDonald** doubt whether the behaviour of tuberculosis mortality in later life can be fitted completely into the cohort pattern; and it is obvious that the mortality of females accords with this pattern less closely than does that of males. The strongest evidence of the importance of contemporary environment is the response of tuberculosis mortality of all age-groups to gross influences, such as war. Let us hope that the considerable falls in mortality since the introduction of chemotherapy will distort the cohort pattern in the opposite direction.

Annotations

REMOTE CONTROL OF EPIDEMICS

The epidemiologist is very like the detective both in s way of reasoning and in his working methods. Like e detective, too, he may be either the armchair type r the man who runs about looking for clues. Usually he anages to find the cause of his disease close to the site f the crime, but two interesting reports suggest that me diseases may operate from a distance.

The first is Murray Valley encephalitis, a disease which roke out in Northern Victoria and New South Wales arly in 1951.[1] Workers in Melbourne isolated the ausative virus[2] and showed by serological tests that a arge number of healthy people, horses, dogs, and wild irds must have been subclinically infected.[3] At the ame time workers in South Australia[4] isolated from a atal case near Adelaide a virus which was identical with he Melbourne virus and closely related to the virus of Japanese B encephalitis. Now, Miles and Howes[5] report he results of further investigations into the epidemiology f this strange disease. Sera taken from aborigines in the Northern Territory in the absence of a recent epidemic howed as high a prevalence as sera from the Murray Valley; and this suggested that the disease might be ndemic in Northern Australia. Presumably the nfection is, like Japanese B encephalitis, primarily one f wild birds, and infection of man is an unfortunate ccident. Murray Valley encephalitis is clinically and pathologically indistinguishable from the mysterious Australian "X" disease, of which three epidemics have been reported. Miles and Howes suggest that Australian "X" disease is in fact an endemic infection of birds in the Northern Territory and Queensland which periodically spills over into Central and Southern Australia to produce epidemics in man. In Western Australia, and presumably also in Northern Australia, the breeding of birds does not depend so much on the time of year as on rainfall. Accordingly, meteorological data from the Northern Territory and Queensland for the past forty years were examined, and a most impressive correlation was found between years of high spring rainfall and epidemics of Australian "X" disease or Murray Valley encephalitis. In seasons with exceptionally early rains birds breed early, and young birds move to the south at a time when mosquitoes and locally bred birds are numerous. As a result, epizootics start in the newly infected area and cases appear in the neighbouring human population. If this reasoning is correct—and it seems reasonable—further outbreaks of Australian "X" disease can be expected when the rainfall in remote Northern Australia is high in the spring. It may be well, however, to remember C. H. Andrewes's comment that epidemiologists have their greatest successes in spotting cycles of past epidemics, and that they are often less successful in prediction.

The second disease that may operate from a distance is poliomyelitis. This infection is commonly supposed to spread by direct contact via infected pharyngeal secretions, although the demonstration by Kling et al.[6] that the virus can be recovered from sewage raised the possibility of fæcal transmission. Fæcal transmission may prove commoner than many people think if epidemiologists are as vigilant as Huss et al.[7] These workers investigated an outbreak of poliomyelitis in Malmö in 1949. They noticed that the incidence of cases was much higher in Malmö than in other Swedish cities, and that the first ten cases occurred at about the same time in people who had had no contact with one another. The possibility of a common source of infection was investigated; and, surprisingly, samples of drinking-water were found to be contaminated with fæcal bacteria. The complex water-supply of Malmö was explored and the infection traced to an uncovered reservoir. A 15-litre sample of this water was concentrated, treated with ether to remove bacteria, and inoculated into monkeys; these animals developed paralysis and histological evidence of poliomyelitis. Virus was found in a second sample of water taken four months later—a result that is in keeping with the known stability of poliomyelitis virus. But how did the virus get into the reservoir? Contamination from sewage pipes was excluded; but the reservoir is close to the sea, into which sewage is discharged, and wild duck and gulls, which had been seen on the reservoir, may have passively carried sewage from the sea. Huss and his co-workers hope that in further experiments they will add the final links to this chain of evidence.

To those who like epidemiological stories there will be the same fascination in these investigations as in a detective story. But perhaps it is best not to confess to too much amazement lest the epidemiologist should retort: "Elementary, my dear Watson."

For suitable patients the procedure is as follows ·

The patient lies on his back on a 'Dunlopillo' mattress placed on three adjustable wooden sections which have a concavity made to suit the curves of the body The perineal region lies over a hole in the rubber mattress, and all excretions pass through this hole by a funnel to a receptacle placed on a rack below If the patient remains in position there should be no soiling of the rubber surrounding the hole, and the patient's skin should never be in contact with his excreta Thus the drawsheet can be given up, and with it the sluicing of the soiled linen, but the patient's back has to receive the usual four hourly attention from the nurses, and the funnel has to be cleaned If the patient does alter his position, the rubber may have to be washed each time Some apparently completely helpless patients even succeed in getting their hands soiled, and their habits make necessary a complete change of linen and the washing of the whole mattress

THE ARNOTT GOWN

The problem of coping with the elderly bedridden patient who constantly and repeatedly contaminates the hands with fæces is of serious moment to nurses Many such patients appear to be perfectly sensible and agree when remonstrated with that their habits are foul In some hospitals the device is used of making them keep their arms outside the bedclothes, but this cannot be done unless the wards are reasonably warm and there has to be sufficient staff to enforce the rule For patients who are sensible enough, occupational therapy is of benefit as a means of keeping their hands employed Some nurses apply a drawsheet like a baby's napkin, but the persistent patient can circumvent any such barricade, and it has the further disadvantage of acting like a kind of fæcal poultice, causing the skin of the back to deteriorate The use of sedatives is effective and justifiable in the insanely filthy, but the doses have to be high, in fairly sensible patients sedatives do more harm than good and by causing mental confusion give them some excuse for their habits The weekly enema is found to be of great benefit and prevents *constant* soiling in those who are well enough to stand it Sister A Arnott has devised a modification of the ordinary hospital nightgown, which can be used in an ordinary bed or with the Brocklehurst bed, and this has been completely successful (Arnott and Nisbet *1952*) When wearing this gown, the patient feels much warmer and her hands remain clean

PREVENTION OF SMELL

Some of the people who live or work in the ward may become accustomed to the smell of an incontinent ward, but not all do, and certainly visitors to the wards are bound to be disgusted if measures are not taken to deodorise the atmosphere A great deal can be done by the regular, frequent, and complete changing of linen and washing of the skin which is carried out in a well-run ward But even so there are bound to be times when some smell is unavoidable, and it is at its worst just after a "purgative night" or an "enema day," when the bowels of many patients move at about the same time

The odour of fæces appears to vary considerably in different patients Nurses report that some patients always have extremely malodorous stools, in others they are offensive only after some digestive upset or when the stools are loose Attempts to overpower the smell by spraying the ward with some strongly scented liquid are not as a rule very effective On the contrary, the combination of an offensive odour with a perfume is often particularly sickening Adequate ventilation is important, but elderly patients seem to have a curious dislike of open windows The use of the Bohmansson toilet chair cannot solve the problem in the incontinent vegetable type of patient, or in very contracted or very heavy patients who cannot easily be got out of bed One solution appears to be to fix the malodorous gas, as with Prof Stanley Alstead's deodorising device, charcoal blanket (Alstead 1942) But that unfortunately is not suitable where there is such danger of its being soiled Moreover, fæcal odours are largely attributable to the presence of sulphuretted hydrogen, and gases with a low molecular weight and high degree of volatility, such as this, are not readily adsorbed on activated carbon Ammoniacal odours, too, easily penetrate a screen of activated carbon, and the charcoal blanket is therefore of no value in minimising the nuisance of this particular kind of smell from incontinent patients Chlorophyll tablets, taken by mouth, which are said to destroy the smell before it reaches the open air, are still on trial

Retention of Urine

In the treatment of retention of urine in the male a few of the more domestic procedures should be carried out before catheterisation is attempted, or the patient transferred to hospital Getting the patient out of bed, hot applications to the lower abdomen, hot drinks, hot baths, the reduction of a hernia, and the administration of an enema should all be tried Carbachol has sometimes an effect but is considered inadvisable when there is much distension and the prostate is enlarged When these measures have failed, the treatment depends on the ease of getting the patient into hospital and the type of treatment advised by the surgeons there

Unfortunately at our hospital there was no close liaison with a urological surgeon, and when emergency admission was impossible, catheterisation had to be carried out to relieve the patient's symptoms Once he had been admitted to a surgical ward, he returned only too often with a suprapubic cystostomy

Wilson Hey (1946) says that the suprapubic tube should be relegated to the museum of medieval prostatectomy and advocates primary suprapubic prostatectomy as being the only clean approach to the prostate He thinks that slow decompression is not only harmful but also unnecessary and that postoperative uræmia is due to infection He advises that the patient should be out of bed every day after the operation even if only for a few minutes Walters (194 too, advises immediate prostatectomy for urinary retention He states that there is no need for gradual decompression with its dangers of infection, either by catheter or suprapubic tube

Riches (1949), however, advises gradual decompression to avoid intrarenal hæmorrhage (A restless patient, confused by pain often disconnects or removes the catheter) He regards suprapubic catheterisation as better than cystostomy and prefers a two stage to a one stage operation He states that the mortality should not exceed 5%

Stewart (1949) reports on 1960 prostatectomies with a 3 01% mortality He describes catheterisation for acute retention after the injection of sterile water soluble lubricant as an alternative he suggests suprapubic aspiration, and he believes that repeated catheterisation has no place in modern treatment Prostatectomy in those suffering from cerebral softening is apt, he says, to cause further mental deterioration. But we can add that suprapubic cystostomy, too, undoubtedly leads to mental deterioration

Jacobs (1948) holds that the establishment of permanent suprapubic drainage as a method of relieving prostatic obstruction is highly undesirable and indeed must be regarded as a confession of failure It may be used as a temporary measure while the effects of renal impairment are treated He describes the numerous methods of prostatectomy—suprapubic, retropubic (Millin), Wilson Hey's immediate prostatectomy, and the transurethral route In a review (Jacobs 1951) of 500 cases of retropubic prostatectomy he found a 6% mortality, in the 80 (16%) patients over the age of 75 the mortality was 8 7% He reports an excellent functional result with ease of micturition, clear urine, complete control, absence of residual urine, and little nocturnal disturbance

This selection from many references gives some idea of the number of methods that can be employed with excellent results, without having resort to suprapubic cystostomy Admittedly these patients with

The elbow and wrist joints remain unaffected. table difference between the two conditions is that, eas the ultimate prognosis of “ frozen ” shoulder is , the “ shoulder-hand ” syndrome may cause re permanent disability. Whether the shoulder-d syndrome is closely allied to the common type rozen shoulder or is a distinct entity has yet to arnt.

BED REST AND REST ETERNAL

HE more we learn about the human body the surer are that it should be kept up and doing. The old, cially, should profit by the hymnist's advice and dread grave as little as their bed ; or as much. Dr. Charles er,[1] however, in reminding us of the dangers of the , is careful also to point out that confinement to it not be beaten as a means of forcing the overtired to . Few of those sentenced to this form of imprisonment plain much after the first day ; for leisure, as we all w, is a drug of addiction. “ There may be restlessness a few days, but then complacency arrives, in the ond week laziness sets in, and later the difficulty may l be to get the patient moving again.”

ut for the old and enfeebled bed rest spells such ngs as loss of tone in the muscles, decline of muscular rdination, stiff joints, postural deformities, pressure es, and hypostatic pneumonia ; while the slowing of peripheral circulation favours venous thrombosis l the risk of pulmonary embolism. Even when they gin to get up they may experience a transient “ effort drome ” because the reflex adjustments of the heart l circulation have become sluggish with disuse. After ong period in bed the aged may never fully readjust mselves, even if their minds have not suffered from diminished mental stimulation which such confinement entails. But by far the worst feature of bed rest a chronic ward, Dr. Baker says, is the loss of hope of y personal independence, to which is often added terness at filial neglect. The geriatricians have hieved a great thing by getting their patients out of d and moving.

The danger of venous thrombosis is now so well preciated that surgeons and obstetricians vie with ch other in getting their patients early out of bed. ysicians, of course, are not so well placed to apply the inciple, but they, too, are less anxious to keep the sick cumbent than they used to be. As Dr. Baker points t, it is not just being in bed that slows the circulation leg veins : it is the fact that the legs are so often *mobile* in bed. The venous flow, it has been shown, increased by even very small movements of the feet. rong normal people kept in bed move their legs, and aintain a normal rate of flow. But patients after erations keep still from fear of pain, and old and feeble ople, as often as not, cannot move because the bed-othes are tucked in too tightly. It seems appropriate urge once again, as we have often done before, that ery patient in a hospital bed should be nursed with a ge over his feet, so that his legs are not pinioned by the eight and tension of their coverings. Nurses are not wedded to the idea of neatness that they will put it efore the well-being of their patients. In a case like is they only need convincing of the value of the measure apply it ; though they will probably not be able to et the necessary equipment without the support of the edical staff. Dr. Baker insists that if patients must main in bed they should be encouraged to move their et ; but adds that this does not absolve their doctors om the duty of examining the legs for painful spots, calised œdema, or localised pain on movement. “ Early rombosis can easily be missed if we look only at the xposed end of the patient or are too chary of disturbing he tidiness of the lower end of the bed.” An active diaphragm, also important in maintaining a good venous circulation, can be ensured by breathing exercises.

He is as convinced as everyone else of the value of bed rest in heart-disease, but offers cogent reasons for not making it absolute. When we are lying, our cardiac output is greater, by as much as a third, than when we are erect. The normal heart, he says, rapidly adjusts itself to recumbency, but this is not so with the failing heart : the patient, when lying, has to cope with increased blood volume and venous pressure, and with relatively hampered respiration. When he is sitting up in bed, with legs extended, his cardiac output is much less, and so is his respiratory embarrassment. But it is a tiring position to maintain, and patients find they sleep best and most comfortably with the body upright in a high-backed chair. He reminds us how patients with left-sided heart-failure ease their discomfort if left to themselves : they prop themselves up with extra pillows, sit up in bed when breathless, and if this is not enough hang their legs over the side—thus diminishing the venous return to the right heart, which is pumping blood into the already congested lungs. In severe attacks they get out of bed and stand up until relief comes, often spending the rest of the night in a chair. “ What unquestioning faith they have in us when we insist on treating their complaint by not letting them out of bed at all.” It is good practice, he says, to advise them to sleep in a chair, especially in the early stages of treatment ; and he emphasises that the best way to treat the acute emergency of pulmonary œdema is to get the patient on to a firm chair. Right-sided failure, with congested neck veins, enlarged tender liver, and general œdema, has usually been preceded by left-sided failure ; so the lungs, as a rule, are congested as well. It is safer and more comfortable, he points out, to have fluid in the legs than in the lungs. The patient with right-sided failure should therefore certainly have periods of sitting in a chair. “ The few steps to and from the chair and a daily visit to the toilet give the heart little extra work, lessen the danger of pulmonary infarction, and pay a rich dividend in improving the patient's outlook.”

Even in coronary thrombosis, he finds, the duration of bed rest may be reduced in mild cases to four weeks ; and it need be absolute only during the initial period of shock. After this he recommends the use of a commode in the bedroom, for it has been well shown that this causes less effort and strain on the heart than the use of the bedpan.[2] Patients and relatives, who are apt to fear that death may result from the slightest movement, can be told that coronary thrombosis most often occurs when the patient is at rest, often in bed, and that the reason for rest is to allow the heart to deal with what *has* happened rather than with what *might* happen.

MECHANISM OF PROTEINURIA

SOME textbooks of general and applied physiology still teach, in Cushny tradition, that in health the renal glomeruli deliver to the tubules a protein-free plasma filtrate, and that proteinuria need only be considered in terms of abnormal permeability of the glomerular capillaries. Monographs of renal physiology, however, mention the alternative, or “ modern,” theory that normally some glomerular filtration of protein takes place and that there is constant tubular reabsorption of filtered protein. Proteinuria could then be due to increased glomerular filtration of protein with saturation of a normal tubular reabsorptive capacity, to diminished tubular reabsorption of a normal protein load, or to a combination of glomerular and tubular defects.

This matter has been debated since the 19th century ; but the balance of evidence, reviewed authoritatively by Rather,[3] *increasingly favours normal glomerular filtration*

COLINDALE

Hub of the Public Health Laboratory Service

In opening the new building of the Central Public Health Laboratory at Colindale, London, on Jan 15, the Minister of Health, Mr Iain Macleod, traced the origins of the Public Health Laboratory Service, paid tribute to the work it has already done, and expressed his confidence in its future It has, he said, grown up in a characteristically British way, and a great deal of its success has been due to the happy liaison between the Medical Research Council and the Ministry

A GROUP OF LABORATORIES

The building itself is a plain but well-proportioned brick structure four storeys high (including the ground floor) It has a copper-covered roof, a central square tower, and a semi-basement, in one or other of which are housed most of the essential services, including, for example, compressors for cold rooms at 4°, —30°, and —70°C, air filters, and a gas-fired incinerator The building is about 170 feet long and 40 feet wide, it contains some 60 working laboratories Its design allows great flexibility for making alterations such as removing or constructing partition walls The basic design of each floor is the same there is a corridor running the whole length of the building with rooms leading off on either side Each floor has a preparation room, sterilising-room, and media making facilities for its own special needs There are main and emergency staircases and three lifts—one for passengers and two for services

The third floor of the new building is occupied by the *Virus Reference Laboratory* This, under the direction of Dr F O MacCallum, has of late years given increasingly valuable help in the investigation of virus infections both in the laboratory and in the epidemiological field. The new building should remove many of the difficulties and dangers which have hampered virus work in the past. Great care is being taken to prevent contaminating organisms from penetrating into the virus research laboratories and virus-infected air from reaching the outside atmosphere One of the two service lifts, for example, is intended to travel non stop between the ground floor close to the virus animal-house and the third floor of the new building Cold rooms at 4°, −30°, and −70°C are situated on this floor conveniently close to the virus laboratory

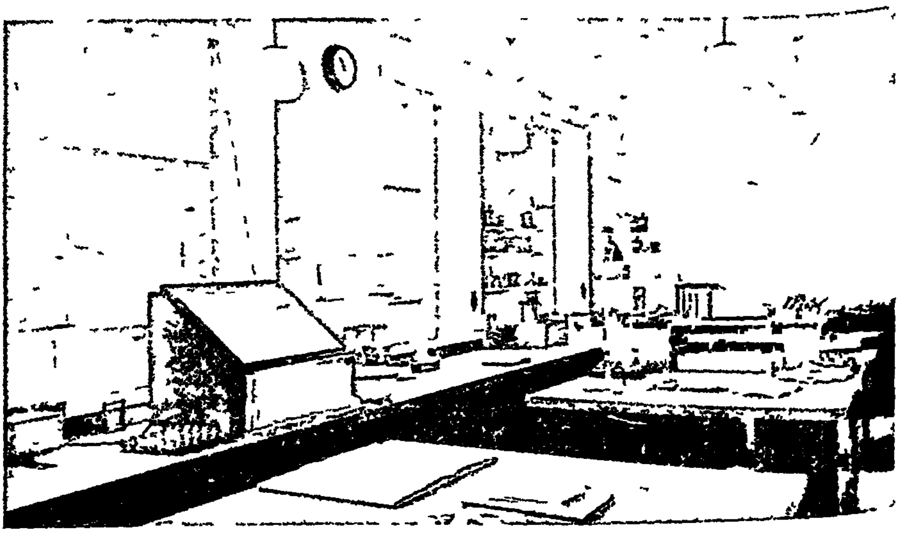
The second floor is devoted to the *Air Hygiene Laboratory* directed by Dr R E O Williams The work here will be done in three main sections

The *streptococcal laboratory* acts as the main reference laboratory for the serological typing of streptococci This has come to be recognised as an indispensable weapon in the laboratory control of streptococcal infections both in epidemic and in inter epidemic times Typing of streptococci is now carried on not only at Colindale but also at some of the regional centres

The *staphylococcal laboratory* undertakes the typing of staphylococci from cases and outbreaks of pemphigus, surgical and other cross infections, and food poisoning, to mention a few of the common sources Typing of staphylococci has proved especially valuable recently in tracking down outbreaks of food poisoning caused by staphylococcal toxins

The study of *air hygiene* will be greatly helped by the provision of special rooms for investigating problems of ventilation and of air disinfection Here, under properly controlled conditions, it should be possible to make real progress in solving some of the baffling problems presented by epidemics of respiratory infections

The first floor is devoted to the bacteriology of food and food-borne infections The *Salmonella Reference Laboratory*, directed by Dr Joan Taylor, has built up a world-wide reputation in the identification of organisms of the salmonella and coliform groups and has also investigated the bacteriology of infantile gastro enteritis On this floor, too, is the *Food Hygiene Laboratory* directed



Virus Reference Laboratory : part of a routine laboratory

starting treatment, and it invariably relapses when treatment stops. But these observations do not carry us very far. Is the action on the hair bulb, the blood-vessels, the autonomic nervous system, or the thalamus? Does it involve a virus, a toxin, or an attitude of mind? An effective answer seems unlikely in the immediate future; but at all events the latest news is hopeful, and promising prospects are opened up by the research tools, A.C.T.H. and cortisone.

THE WORLD'S SOCIAL CONDITIONS

RECENTLY we welcomed a small pamphlet entitled War on Want, issued by the Association for World Peace, as "a sober account of world poverty."[1] A large monograph[2] on this subject has now been prepared by various United Nations special agencies at the request of the General Assembly. This deals with population problems, health conditions, food and nutrition, housing, education, conditions of work and employment, and general levels of income and welfare. There are special chapters on social conditions in Latin America, the Middle East, and South-east Asia. Such a great mass of factual information has been assembled and critically examined that the book is likely to become a standard reference work for students of any social subject who are interested in world affairs.

An introduction discusses the effect of modern scientific technology on our outlook. In the basic ethics of all great religions it has always been recognised that the rich must help the poor: now arising "from this deep impulse of human charity and consistent with voluntary help and personal giving" governments have accepted the principle that the rich countries must help the poorer countries to develop their material standards of living. Such well-doing is "enlightened self-interest." All over the world fatalistic resignation to poverty and disease is being superseded by a demand for a better life, made possible by scientific discoveries. This demand is at the back of nearly all the political unrest in the world today. Unfortunately it is only too often exploited by wicked and ignorant men; nevertheless, as this report abundantly shows, there is often real justification for "unrest," which needs to be directed into creative channels.

The chapter on health, prepared by W.H.O. staff, provides striking contrasts. A map shows the present world-wide distribution of malaria, and the results of modern control methods are described. In the Himalayan Terai, in the Uttar Pradesh State of India, there is a fertile tract of over 2000 square miles; here over a thousand years ago the cultivators were driven out by malaria and the jungle was allowed in. Now, however, malaria control has already enabled man to throw back the jungle and so provided thousands of fertile farms for new immigrants. Most of the cost is falling on federal and State governments, but W.H.O., UNICEF, and F.A.O. are providing some material aid in addition to much technological skill. The effects of malaria control on productivity are immense. In Greece D.D.T. has had the effect of adding an equivalent of between 100,000 and 200,000 healthy workers a year to the labour force. The report makes it clear that in the fight against mass diseases, such as malaria, yaws, tuberculosis, and schistosomiasis, most countries need not only more doctors, nurses, and equipment, but also more and better food and educational services to combat ignorance and age-old superstitions and prejudices. The chapters on other social problems must fascinate the medical reader; for they show how much medicine has to contribute and how closely it is linked with technical problems of food-supply, education, industrial welfare, and housing. The report repeatedly illustrates causal bonds between poverty and disease.

The report is concerned more with statements of general problems than with details of methods for their solution. Accounts are, however, given of many successful ventures in scientific international coöperation, which "may be a means of solving problems that appear insoluble when viewed within the frame of national resources: and thereby the vast gap between the more-developed and the less-developed countries may be reduced. Many pioneer projects and demonstrations are under way." The campaign against yaws now being undertaken by several governments in South-east Asia with the help of W.H.O. and UNICEF is an excellent example. The early successes of the technical U.N. agencies (F.A.O., W.H.O., UNESCO, and I.L.O.), though still small in relation to the problems before them, give rise to a subdued optimism, which runs right through the report. At this time, when the failures of the United Nations on the political side are obvious and are widely publicised, we should remember the successes of the specialised agencies in promoting technical advances in many parts of the world. Scientists are developing techniques for international coöperation which politicians may perhaps copy.

A JOURNAL FOR PRACTITIONERS

IN transforming itself from a weekly into a monthly the *Medical World*[1] has become a very different journal. It ceases to be the official organ of the Medical Practitioners' Union, and its editorial pronouncements will henceforth be independent. A supplement expounding the policy of the union and edited by its general secretary will be sent to every member with his copy of the *Medical World*; but the journal itself, which now bears the aspiring subtitle "the journal of general practice," will be addressed to a wider audience. With the coming of the National Health Service, the issues before the practitioner have become less controversial, but are no less important: "general practice in Britain is about to find itself in the forefront of medical and social evolution," and there is much need to describe and discuss the merits and demerits of new patterns of practice and new ways of organising the work. The *Medical World* also wants to encourage research by publishing the original work of practitioners:

> "It is to fill a gap in British medical literature, to provide a journal written for and, as far as possible, by general practitioners. That is not to say that the specialists and consultants will be excluded from its pages; but they will be admitted as equals, with experience and knowledge to exchange, and not as superiors to pontificate and condescend."

The journal sets its tone in a series of able editorials, written in this vigorous way, and if its contributed articles maintain the level they reach in the first number it will attract and keep a great many interested readers. The accessory items, such as its letter from France, its Impressions of Parliament, and its literary musings, are highly readable—which some authorities regard as the first journalistic virtue—and it offers solid benefit in such articles as the one describing the group practice at Skipton which has lately been visited by the Minister of Health.[2] Here a main surgery was constructed in 1939 from a row of four small houses, and the five partners are now able to tell us how, with the aid of seven ancillaries (definitely excluding wives), they have preserved both their standards of work and their private life. Certainly a most encouraging example, and one which justifies the editorial belief that "we have certainly not heard the last word on the planning of general practice by practitioners. This is not the end but the beginning."

fortable armchairs has been followed since with new curtains, bed-jackets for the women patients, a regular supply of picture papers and other periodicals, a grant for a library, a piano for a convalescent home, a piano-accordion for a blind patient, and wireless installation with headphones in each ward An annual outing has been arranged for patients who are strong enough to enjoy it, and there are monthly bus rides for others, films are shown in the wards, and visits arranged to the pantomime and to Bertram Mills's circus (the Mills brothers, it seems, are great friends of the hospitals) Services for different denominations are held on Sunday evenings and are broadcast to the wards Thus, as the Minister said, is a wonderful record, which can be matched by those of many other local leagues

But the pattern of social effort is uneven over the country In many hospitals there are problems which could easily be solved by a league of friends, and he drew attention specially to the plight of the mentally ill, of the chronic sick, and of the young chronic sick, who so often live out their lives among the aged and dying He would dearly like to see voluntary effort concentrate on these groups, and if it is not yet possible to find a body of friends for every hospital, then let the friends find their way into the old barrack-like hospitals first He recalled a saying from a King's Fund report—that as people grow older their world grows smaller, and each pleasure and each grievance is correspondingly magnified Loneliness is the worst misfortune of age, and it is in the hands of the local leagues to allay that He reminded the meeting that there is a tremendous field waiting in the mental hospitals, for 42% of beds in this country are for the mentally sick, and the waiting-lists are formidable Occupational and art therapy, he suggested, offer opportunities for helping such patients, since—to quote Cowper—

> "Absence of occupation is not rest,
> A mind quite vacant is a mind distress'd"

Here the league, as he reminded his audience, can call on the experience of Mr Adrian Hill, the pioneer of art therapy, who is among its vice-presidents

The Minister was able to reassure the league about a number of matters on which it has been feeling anxiety Thus, far from regarding it as wrong for the chairmen of hospital management committees to form or initiate local leagues of friends, he is fully in favour of it It does not matter who forms these groups as long as they are formed Nor is there any objection to their holding meetings in the hospitals they are befriending, on the contrary the closer the contact between the friends and the hospital the better Again, there is no reason in the world why the matron and other hospital officers should not come to the meetings, and every good reason why they should Hospital management committees are appointed by the regional hospital boards, but he saw no reason why the boards should not consult the league when making their appointments, or why the league should not submit names to the boards for consideration The regional boards themselves, and the boards of governors of hospitals, are appointed by the Minister, but the National Health Service Act requires him to consult various specified bodies (such as the universities) and also those bodies which appear to him to be interested Mr Macleod had that day added the name of the National League to the wide range of bodies to be consulted

The prestige of the league with the Ministry is thus evidently high It has been further raised by the consent of H M Queen Elizabeth the Queen Mother, to become the Patron, as was announced by Mr J P Wetenhall, the chairman, in the course of the meeting A graceful and appropriate emblem has been designed for the league by Mr Adrian Hill

Medicine and the Law

Death Due to Butazolidine

At an inquest on a 44-year-old woman in Nott on Jan 15, the city coroner recorded a verdict of " from bronchopneumonia following agranulocytosis by butazolidine therapy"

Dr H M Rice, senior pathologist at Nottin General Hospital, said that during the past butazolidine had come to the fore as a drug for diminishing or abolishing rheumatic pain People were undoubtedly benefiting by it, 100,000 patients had been treated in this country alone Toxic reactions were, however, being reported, and of these the most serious was agranulocytosis He was of the opinion that the drug should only be administered in hospitals with facilities for daily blood counts by trained staff

Dr Rice said that the medical profession was placed in an extremely difficult position when the general public saw articles in the popular press describing new drugs that were only in the experimental stage "The public think these drugs are cure alls and demand them from their doctors, who must warn their patients that the drugs are not free from risk The patients reply that they have suffered pain for twenty years and are prepared to take a small risk to get rid of the pain It is a difficult ethical problem"

Public Health

Maternity and Child Welfare in Glasgow

Dr Stuart Laidlaw, medical officer of health for Glasgow, in his report for 1951 discusses the downward trend in infant mortality

"Within the past two years," he says, "there has been a tendency for certain writers, particularly politicians, to assume that the marked reduction in infant mortality now implies that the maternity and child welfare work has attained its ends and can now be maintained by a caretaker staff The truth is that the present reduction is really due to the elimination of the most easily preventable deaths and the service is now faced with the more difficult task of maintaining the present standards and improving them in many directions That further improvement is possible is shown by the fact that Glasgow's figures are still nearly double those prevailing in Aberdeen, for example Of course, our problem of gross overcrowding is unique and is unquestionably a major factor in the relatively high infant mortality rate in the city Among the many causes of infant deaths in which considerable further reduction could be attained are prematurity, gastro enteritis, burning accidents, and overlaying Prematurity is still responsible for more than half the neo natal deaths, and although the number of deaths from this cause has been reduced the reduction has been achieved at relatively great expense by special provision for the care of the premature child both in hospital and at home The prevention of prematurity is our aim, and this is closely allied to the ante natal care of the mother Infant mortality from this cause can be still further reduced by a standard of maternal care which ensures that the expectant mother receives optimum ante natal supervision with proper attention to diet and general hygiene Pre natal dietary carelessness is still far too common, and education of the expectant mother to avail herself of the facilities provided and to follow the advice given is still vitally necessary

" a closer liaison between the general practitioner and the maternity and child welfare department would benefit both the curative and preventive services It is disappointing that little advantage is being taken throughout the city by general practitioners of the clinic and other facilities provided for the examination of the blood from expectant mothers There is no excuse for the deaths (approximately twelve annually) which are due to failure to ascertain the Rhesus factor during the ante natal period Yet only half the mothers are tested for Rh" ients, and 33 armchairs and 176 suits available for male "up" patients. There were no wheel-chairs, rt from uncomfortable dilapidated bath-chairs. The rds were as cold and draughty as ever, and fires were nounced unnecessary for people who should either be bed or in part III accommodation.

These circumstances were easily reconciled with the despread desire to preserve at all costs the status quo. it the work still went on; the "up" patients increased ily in number, and were to be found even in the wards the most conservative and fastidious sisters. Hardness seldom encountered among nurses who actually work ith patients: what is proved to be good for the human ings under their charge is incontrovertibly good in eir eyes, and they do it with all their might.

The "Wee Turn"

The elderly are liable to sudden transient episodes of unconsciousness of varying duration, whose occurrence ends to cause the patient to be kept in bed. The different ypes described below may not be varieties of the same ondition with the same ætiology (whatever it is), but they have been seen in the same patient at different imes.

The briefest variety usually occurs when the patient s sitting in a chair; he is noticed to look vacant for a moment and may drop anything he is holding, then quickly returns to normal—a description suggestive of petit mal. Or he may become very pale, lose consciousness, and slide off his chair; but recovers immediately and completely when returned to bed, knowing nothing of what has happened. A recent meal, getting up in the morning, proximity to the fire, a warm close atmosphere (as during a film show), or excitement (at film show or ward party), may be precipitating factors; but attacks indistinguishable from these may occur on getting up for the first time after many years lying in bed, in gross anæmia, severe nausea, vomiting, diarrhœa, or internal hæmorrhage (confirmed by the subsequent appearance of hæmatemesis or melæna). Sometimes a patient may have several such attacks on successive days and then be free from them for weeks.

There are also attacks of longer duration than those just described. The patient remains unconscious for a longer period and recovers more slowly. He is very pale, sometimes slightly cyanosed, with cold extremities and feeble or imperceptible pulse, but neither tachycardia nor bradycardia. The breathing is quiet; there is no twitching, and no evidence of a lesion of the central nervous system. Sometimes there is incontinence of urine or of a very loose stool. He usually recovers gradually when returned to bed, and improves if given brandy as soon as he can swallow. He is as a rule rather vague at first, but may say that he felt dizzy or very sick, and sometimes vomits on regaining consciousness. A few patients, however, with exactly the same signs, die a few minutes later, before or after regaining consciousness, without further clinical sign or symptom—presumably of a coronary thrombosis.

Occasionally the appearances are exactly as above, but the patient does not immediately recover consciousness, though the pulse becomes palpable again and the colour improves. On examination he is found to have a definite flaccid hemiplegia. The blood-pressure is usually at the patient's normal level—of about 160/90 mm. Hg. The appearances are those of a cerebral thrombosis, but the breathing is quiet, not stertorous. The patient may remain unconscious for as long as twelve hours, then regains consciousness and is found to have no evidence whatsoever of a hemiplegia; he is usually up and about as usual within twenty-four hours. This may be repeated in the same patient several times.

Transient hemiplegia is also seen, accompanied by unconsciousness, flushing of the face and twitching of one side of the body; in such cases the pulse is unaltered. These patients often develop a permanent paralysis after several such attacks.

There is also the sudden weakness, especially of the legs, which occurs when the patient is either standing or sitting and which makes him completely helpless; it is not accompanied by loss of consciousness or alteration in the volume of the pulse, but he sometimes becomes rather pale, and reports that he felt "completely done." Such attacks are usually transient, but are on occasion the reason why old people living alone are found on the floor having lain there many hours or even for days, because they were unable to rise.

The following case-histories illustrate some of these attacks.

Case 1.—Mrs. B, aged 84, was a very pale woman with a hæmoglobin level of 7 g. per 100 ml. She had several brief attacks of unconsciousness, usually on rising in the morning, with quick recovery on return to bed. Since her anæmia has been corrected she has ceased to have such attacks.

Case 2.—Mrs. C, aged 76, has a slight right hemiplegia. For four years she has had brief attacks of unconsciousness when sitting up in a chair; she becomes pale and pulseless and recovers gradually when returned to bed. These attacks were the reason for her being kept in bed for many years. Often she has none for weeks or months, then several in one week. She is not anæmic and her blood-pressure is 150/90.

Case 3.—Mrs. D, aged 80, on several occasions became very pale when sitting in a chair after dinner. Her pulse was impalpable and her extremities very cold. She recovered gradually when returned to bed but was rather vague in manner; she could only say that she felt very sick; on one occasion she was doubly incontinent. She eventually died suddenly one night when convalescing from pneumonia.

Case 4.—Mrs. E, aged 72, is a diabetic and is blind. One day when sitting in a chair after dinner she became deeply unconscious and fell from her chair. She was very pale, but not cold, her pulse very feeble (70 per min.) and her breathing quiet. There were signs of a complete flaccid left hemiplegia. She remained unconscious for twelve hours; twenty-four hours later she appeared to have recovered completely; there was no sign of any paralysis and she was able to walk as before. The blood-sugar at the time of the attack was 200 mg. per 100 ml. There has been no recurrence (in 12 months).

What is the ætiology of these attacks in the elderly? Some are so transient that little or no investigation can be made. The pallor, the cold extremities, and the imperceptible pulse suggest a primary cardiac condition (possibly caused by vagal inhibition) with secondary cerebral anæmia leading to unconsciousness, and in some cases signs of paralysis. The patients have no obvious signs of heart-disease, their blood-pressures are not excessively high; their pulses are of a normal rate and rhythm.

Sir Thomas Lewis (1946) divided "attacks of fainting" into the following:

Postural Faintness.—Temporary giddiness or transient loss of consciousness on rising, usually in middle-aged or elderly people, especially on rising from a chair after a full meal in an overheated room.

Vasovagal Attacks.—Seen especially in the young in poor health, fatigued or fasting. It is a brief attack causing a sinking feeling in the abdomen, nausea, loss of consciousness, pallor, and imperceptible pulse. A similar attack occurs in those with aortic regurgitation.

Cardiac Syncope.—Rare compared with the other causes of fainting. He considered that most are cases of chronic heart-block; a few are due to temporary heart-block; and there are a few rare cases in which the whole heart stops beating for a few seconds. Sudden death is probably due to fibrillation of the ventricles.

Of the differential diagnosis of fainting he wrote:

> "Postural giddiness and vasovagal attacks in middle-aged or elderly people are apt to be attributed to cerebral arterial disease and regarded as attacks premonitory to apoplexy; such cases are differentiated by the absence of profound pallor or heavy sweating, the unaltered pulse, and the association of loss of memory, paresis or aphasia."

Letters to the Editor

CHILD-WELFARE CLINICS

SIR,—I read with considerable interest the contribution by Dr George, Dr Lowe, and Professor McKeown in your issue of Jan 10 Their account of the work done at clinics, and the reasons for attendance, accords with my own experience, and I agree wholeheartedly with their principles and conclusions But I cannot endorse their suggestion that an increased capitation fee should be paid for children on the lists of general practitioners prepared to provide a full child-health service from local-authority clinics

In an urban area such as Birmingham, the children attending any one clinic are patients of several practitioners If all these doctors elected to provide a full child-health service it would be impossible to organise a clinic session for each of them On the other hand, if only one or two doctors undertook the service, they would be seeing children at the clinic who were patients of their colleagues and for whom they would not be responsible outside clinic hours—a perpetuation of the present unsatisfactory system

The analogy with midwifery is clear, and in midwifery we have seen a marked reduction in attendances at antenatal and postnatal clinics It was never the intention of the National Health Service Act that all general practitioners should practise midwifery and carry out their antenatal examinations in their surgeries, but the incentive to do so has been too great

Because some practitioners' lists will now have to be reduced to the agreed maximum of 3500, the present is a very suitable time for a general revision The following scheme would, I believe, solve many problems and have a fair chance of success Since

(a) the supervision and treatment of children can be conducted more satisfactorily from a local authority clinic or health centre than from a general practitioner's surgery,
(b) it would not be practicable to arrange clinics for all general practitioners at which each practitioner could see his own patients, and
(c) it is undesirable that a doctor at a clinic should treat children who are on other doctors' lists,

the following proposals are made

1 All children under 5 years of age should be removed from practitioners' lists
2 Only those doctors willing to provide a full health service for children, including clinics and domiciliary practice, should be allowed to take children on their lists The capitation fee would be greater than that paid for other patients, the increase being refunded to the executive councils by the local authorities, which would no longer have to pay the salaries of assistant medical officers
3 Inclusion of children on a doctor's list would be made at the clinic to ensure that so far as possible the children would be identified with a doctor and a clinic serving the area There would of course be a free choice of clinics by the mother
4 The present clinic medical officers would be allowed to take children on to their lists provided they were prepared to provide a full health service including domiciliary care They are at least as well qualified as their colleagues in general practice to undertake this work

It will be objected that this scheme is inimical to the concept of the family doctor In many families, however, the individual members are on different doctors' lists, and this is especially the case with children, the mother stating that she takes her children to Dr A because he understands them better than her own Dr B Again, not all doctors are keen on work among children, and many would be glad to hand it over to their colleagues

It is significant that, of the mothers questioned a clinics, "the remainder (almost half) gave suggesting dissatisfaction with their general pra service the surgery was too far away, a surgery was no place for a child, afternoon cons was more convenient, or the doctor was abrup or too busy to make even a cursory examin Long waiting periods are another frequent ca complaint

I was interested to learn that some general prac do their antenatal and postnatal work at local an clinics In my area many practitioners would see their maternity cases at the clinics, but our insuperable difficulty has been that the patients at on any particular clinic day are on the lists of as as six different doctors Possibly a solution c found along the lines outlined above for child clinics—i e, that only those practitioners willing t full antenatal and postnatal care to their pa from local-authority clinics should be allowed t maternity cases

If both child-welfare and maternity clinics were conducted as suggested, it should be reasonable to arrange for periodic consultant sessions, o and pædiatric, with all the advantages these bring Obviously the integration of these services have been simplified had health centres been avail but the above scheme would be applicable with ex facilities and could be continued and improved t the health centres of the future

H TABB
Oldbury Area Medical Of

MITRAL STENOSIS

SIR,—In your annotation of Jan 10 about our pa on the dynamics of mitral valvular disease yo several pertinent questions

Firstly, the more benign clinical course of pat developing massive left auricles is of great intere is probable that the most important single factor in production of symptoms in mitral disease is pulmo congestion A massive left auricle, large enough to do the capacity of the pulmonary venous reservoir, wo tend to lead to lower pressures and also to pre sudden large increases of pressure Furthermore, th patients generally fibrillate early, and this also tend lower pulmonary pressures Tricuspid insufficiency, diminishing right ventricular efficiency, may well in the same way

Secondly, it does not seem surprising that Broc and others should find at operation that the orifi of the stenosed valves are of a fairly uniform size T in-vitro experiments of Gorlin and Gorlin[3] have sho that, for a given flow, the area of an orifice is inver related to the square root of the pressure gradient acr the orifice multiplied by a constant of 31 If there is incompetence (and gross incompetence, at any rate, probably excluded by selection), a small difference area will lead to a large difference in pressure gradie Thus, for a given output of 6 litres per minute, increase in the area of the valve orifice from 1·04 1 27 sq cm leads to a fall in pressure gradient fr 30 to 20 cm of water Such a difference in pressure make a considerable difference to the degree of pulmo congestion, but it is doubtful if the exploring fi of the surgeon would detect a difference of one or millimetres on the major or minor axes of an irreg elliptical valve orifice

It is more difficult to accept Brock's contention in slight symptom-free cases of mitral stenosis the la is an oval of not more than 1 5 by 0 75 cm

---

om delay going until it is too late. Many patients our hospital were admitted incontinent from part III commodation for this reason, but were perfectly ntinent in hospital. Toilets should therefore be easy access and warm, and there should be sufficient handils on the way to them. The use of commodes for mi-ambulant patients during the day should be voided if possible; they should be helped to get to he toilet or wheeled in the Bohmansson toilet chair Bohmansson and Malmros 1947). Ideally all commodes hould be permanently screened, but this arrangement ould bewilder many of the frail elderly, and some would ip over the feet of the ordinary ward screens, or try o support themselves by holding on to them. Nevertheless it may be a fact that certain patients are deterred rom using commodes because of the lack of privacy.

In patients with fæcal incontinence, examination may eveal a loaded rectum, causing retention with overflow; epeated enemata should then be given until the bowel s clear (Cosin 1947, Warren 1950). For those who are egularly incontinent of fæces, some ward sisters find hat a regular weekly enema is useful (advised also by Adams 1949 and Amulree et al. 1951); apart from one day there is little soiling; it may however be several weeks before the benefit is apparent. The weak and frail cannot be treated in this way, for some of them become cold and collapsed after an enema. For those who, in spite of routine enemata, have filthy habits and who cannot be got out of bed, sedatives may be the only possible form of treatment; patients of this type who are up and about should be kept in the ward if possible as their habits are often better in public than in the privacy of the toilets. There are also those who have no reason to be incontinent and appear perfectly sensible: they sometimes improve after a serious talk during which extreme disgust is shown and the question of their sanity raised. It is important that such patients should not be mixed with the very degenerate as they seem to take the view that they have as much right to be incontinent as the others. This has been noted also by McEwan and Laverty (1949).

Patients who suddenly become incontinent of urine should be examined to see if the bladder is distended, or if they have a urinary infection. Though in some the treatment of a urinary infection does not alter the incontinence, there are many in whom the incontinence is simply a result of frequency and precipitancy, and the pain caused by trying to suppress the desire to micturate. In some patients a week's course of a sulphonamide is sufficient to stop the incontinence, even though the infection microscopically and bacteriologically persists.

Those who become incontinent as a result of a general infection, cerebral thrombosis or cardiac insufficiency, should not be relegated to incontinent wards, as the condition is often only temporary; and in fact the cessation of incontinence usually indicates general improvement. Wilson (1948) found that many cases improved as a result of gradual distension of the bladder with fluid and inhibitory re-education training. This, however, requires a coöperative interested patient, anxious to overcome the distressing disability. Wilson quotes Allen as writing in 1733 that "in old persons incontinence is altogether incurable unless hot baths relieve them."

Many expedients devised to cope with the problem of incontinence are purely palliative and do not constitute a cure. They accept and in fact condone the patients' failure to remain continent and are intended to make things easier both for the patient and for the nurse. In the male patient, the urinal can be strapped between the thighs. This may lead to excoriation if the skin is not washed often enough. Amulree et al. (1951) recommend condom drainage in men, either in bed or up in a chair. Chapel (1951) describes a modification of this as the 'Simplic' bed incontinence appliance. Incontinence appliances such as the "frequency bag" for ambulant male patients can be of value if the patient is intelligent and of clean habits.

Incontinence appliances for women are usually unsuccessful, and cause pressure sores and areas of excoriated skin. Some who have merely a little dribbling benefit from a napkin, but if there is too much the skin again suffers. Amulree et al. (1951) advised sitting on a commode chair on a rubber ring; again there is the difficulty of giving the skin adequate attention.

Many drugs have been tried for the relief of incontinence—usually of the belladonna, ephedrine, or muscle relaxant type, but without consistently good results (Brocklehurst 1951).

Fortunately, getting the incontinent patient out of bed usually stops the incontinence. Cosin (1947) remarks: "Get them up in a suit of clothes, sit them up to the table at meals, take them to the lavatory at frequent intervals—and they will relearn the habits of childhood." Adams (1949) states that most respond when up, even if only in a chair, though the incontinence often recurs at night. Crockett and Exton-Smith (1949) found that incontinence largely disappeared with the awakening of the patients from a state of mental apathy.

At our hospital these findings were confirmed. Only a few patients were occasionally incontinent when up, and most of these were unable to walk; and instead of being very wet, as in bed, were merely a little damp. A few were incontinent when they were assisted to rise from a chair or when they failed to get to the toilet in time. Those who forget should be taken frequently and regularly in spite of protests. Incontinence in bed at night usually persists for a longer time, but with increasing mobility and lessening of apathy this too disappears. The few "accidents" that occur in the initial stages of rehabilitation are apt to discourage the nurses. But soon, forgetting this initial prejudice, they begin to tell the doctor that *of course* such and such a patient is not incontinent when up. Victory may be regarded as won when a nurse volunteers the information that "We were so short of staff at the weekend and the clean linen was almost finished, so we just *had* to get the patients up." In one ward where formerly 48 drawsheets and 48 short gowns had to be sent to the laundry every day, only 11 drawsheets and 5 short gowns were used daily after four months' rehabilitation of the patients.

Of 58 female patients who were always incontinent (31 doubly) in bed, and who are now up in chairs or walking about, 52 are never incontinent when up; 6 are occasionally incontinent of urine when up; 23 are completely continent even in bed and asleep.

It has been found that it is usually those who are unable to walk who are incontinent when up; and a good nurse will often blame herself and say that she was too busy to assist the patient at the right time. Those who remain incontinent in bed have either not been ambulant for very long or are of the bovine apathetic type.

THE BROCKLEHURST BED

The Brocklehurst bed accepts the incontinence as incurable, and makes a virtue of immobility. The patient must be able to lie flat on his back, and must be sufficiently helpless or apathetic not to roll or turn from side to side or shift his position up or down; he must not have more than a slight degree of contracture of the lower limbs. Once the principle of rehabilitation has been accepted, it is found that there are remarkably few patients with the above qualifications; and most of those who are irremediably bedridden and incontinent have contracted knees. These will in any case become fewer as the teaching of geriatrics advances.

TERRAMYCIN IN SALMONELLA INFECTIONS

SIR,—I feel that Dr Watson's letter (Jan 3) may give rise to undue optimism regarding the value of terramycin in these infections

Recently, I treated a *Salmonella typhi murium* carrier, aged 5 years, with this drug The dose used was 400 mg thrice daily to a total of 5 g—i e, approximately 4 days' treatment This dosage in a boy weighing 46 lb is comparable to the dosages cited by Dr Watson and was the maximum amount I could obtain from the South London Blood Transfusion Depot for the treatment of a boy of that age The organism was absent from the stools 6 days after completion of treatment, but 2 days later it was again present His stools have since remained persistently positive

Similar temporary reversion in the carrier state may be obtained by use of chloramphenicol

One of my patients—a carrier of *S enteritidis*—did become permanently negative after a course of terramycin The evidence of the beneficial effect of terramycin was in this case vitiated by the fact that immediately before treatment the number of organisms decreased spontaneously There is a risk of giving too much credit to drugs exhibited when natural recovery from the carrier state is taking place

Waddon Hospital,
Croydon
J J LINEHAN

SIR,—Recent correspondence on the value of terramycin in salmonella infections prompts me to record the following case

A male child, aged twenty months, was admitted to hospital with enteritis due to *S paratyphi B* He was treated with chloramphenicol ('Chloromycetin Palmitate,' 4 fluid drachms, followed by 2 fluid drachms six hourly for eight days, and 1 fluid drachm six hourly for a further six days) Though he improved clinically, he continued to excrete the organism in his fæces He was then given a combination of sulphathiazole and penicillin, and later streptomycin by mouth, but without effect

The organism was shown to be sensitive to terramycin, though unfortunately a quantitative result was not given

Three months after admission, the child was given terramycin 400 mg, followed by 200 mg four-hourly for eight days Four successive rectal swabs were then negative for *S paratyphi B*

During a recent epidemic of paratyphoid B in this area, it was found that though there was a fairly rapid clinical improvement in cases treated with chloramphenicol, many of these patients continued to pass organisms in their stools, often for two or three months and even after a second course of the antibiotic Terramycin may be of value in these cases

MARASMUS TODAY

SIR,—May I thank you for your exposition (Jan 10) of renal acidosis and idiopathic hypercalcæmia as causes of marasmus, and may I ask that in the differential diagnosis the effect on infants of the absence of maternal care be included

Chapin [1] prevented deaths from marasmus by placing infants in foster-homes instead of institutions, that wise pædiatrician, Brennermann,[2] had a rule that babies in his hospital were to be picked up and carried around several times a day, Bakwin [3] showed how infants in hospital showing successive infections and progressive loss of weight became afebrile and gained weight from the day they returned home to their mothers, in this country Sir James Spence and Prof Alan Moncrieff have for many years taught the importance of humane care of babies in hospital

I would like to think that failure to thrive from this cause does not exist today in this country, but it does, for I see the results at times, so that it is wort naming "loneliness in infancy" as a cause of ma in infancy

THE ANKLE BLOW-OUT SYNDROME

SIR,—I would like to cross swords with Mr C and Mr Elgan Jones over their conclusions concerning the ætiology of leg ulcers

Their careful observations agree substantially those of most workers except at one point Th that incompetence of the valves is strictly loca the lower perforating veins, and that the valves in the deep veins are healthy (figs 6 a I would not quarrel with their findings on th but the anatomical presence in the cadaver of a rently healthy valve may not correspond to a fun valve in the living patient Large series of phleb in fact indicate that the deep veins do often extensive valvular incompetence, nor do the radi published by Mr Cockett and Mr Elgan Jones ex this possibility in their own patients

On general pathological grounds, one might expect incompetence to be extensive rather than strictly l to the lower perforating veins, since recanalisati thrombosis is so often the cause Nevertheless, in cases there is no theoretical reason why it should no What, then, is the accompanying pathology? Mr C and Mr Elgan Jones state that infection constantly with each of the four groups of factors leading to ulce with local thrombosis rapidly supervening The sup part of a perforating vein in the base of an ulcer can escape the thombosis—operation amply confirms th tion The deep part of the communicating vein remains patent as a blind diverticulum of the deep but a superficial block is no less effective for being so, all the cutaneous tributaries are likewise involved block, being in effect akin to the local ligature op proposed by Mr Cockett and Mr Elgan Jones, mi expected to cure the ulcer if there were no valvular i petence elsewhere That self cure does not occur in way suggests that we are arguing from a false hypot and that, contrary to the authors' assertion, there mu valvular incompetence elsewhere

Like any other form of reciprocating pump, the mus venous pump in the leg is only effective in the presen adequate valves It is further not just one but a ser pumps in line from below upwards, each consisting segment of vein with an inlet valve at its lower end and outlet valve at its upper end The diastolic pressure at t lower end of each is limited to the height of the column blood contained in each segment—i e, a few inches of w The systolic pressure is a function of the muscular f applied laterally to the walls and the resistance above outlet valve Mr Cockett and Mr Elgan Jones cite a f of 100 mm Hg, but it must be noted that a raised sy pressure will only be recorded in the upper two thirds of t leg, where the muscle bellies provide the necessary f Only if the deep veins show incompetence of their va *in this portion of the leg can a raised systolic pressure* transmitted to the lowest third of the leg

Now Mr Cockett and Mr Elgan Jones emphasise th incompetence is only found in the lower perforating ve and that these "are situated just *below* a powerful mu pump" They specifically draw attention to the fact t in their dissections valves are always "present in veins posterior tibial bundle" (fig 7) In these circumstan systole cannot affect the pressure in the veins *below* pump, whatever the state of the valves there Similar the diastolic pressure in the lowest third of the leg transmit through a perforating vein cannot show a rise due to incompetent valve greater than the difference in le between that valve and the next functioning valve at —i e, no more than an inch or so if the authors' content are correct That in fact both systolic and diastolic ve pressures are considerably raised in leg ulcers suggests th the valvular incompetence is far more extensive than admitted in their paper, involving the deep veins in th upper two thirds of the leg and higher tostomies do not figure as operative deaths: they discarded to chronic institutions, still attached the bed by means of tube-and-bottle. They endure existence made wretched by the debilitating effects a chronic urinary infection and the repeated pain bladder washouts and changing of tubes, in an ever- ting smell of heavily infected urine and rubber tubing. eir whole life becomes centred on the wound and the be; their habits deteriorate; they gradually curl , often under the sheet, and usually die within a year operation. Surely it would be preferable to give such tients a chance of survival, even if it were only a slight e. It is possible to get a few of them up soon after eration with a special belt and bag, and train them to ok after it themselves in a hygienic manner. They ay even go home for a time and have the tube changed a district nurse; though they usually return with mptoms of ascending infection and uræmia.

Case 5.—Mr. F, aged 69, in part III accommodation, found fficulty in passing urine one morning, but did not mention to anyone, because he was very anxious to go out on pass. was a very cold day and he had several drinks "to warm mself up." He returned at night with acute retention of ine. A hot bath and an enema gave no result and he was ansferred that night to a surgical ward in another hospital. ive weeks later he was returned to our hospital with a prapubic cystostomy. He was kept in bed to allow the be to drain continuously. His habits deteriorated. When en six months later his knees were contracted, his urine avily infected, and bladder washouts and the changing of e catheter were causing him much pain. He died nine onths after the operation, with signs of uræmia.

Fractures

Flemming (1951) states that the rules governing the eatment of fractures in the old do not differ from those niversally applicable to the treatment of injuries in eople of all ages. Too often it is found that a lower tandard of treatment is given to the old than to the oung, because it is not thought worth while to restore mperfect function. He points out that the object of the urgeon is to restore to the patients that degree of ctivity which they enjoyed before the accident, and iot some measure of activity which they enjoyed many years earlier: it is wrong to assume that, because they annot be made fit to walk three or four miles, there is no point in enabling them to potter about their room and do an occasional bit of shopping; and there is no justification for fobbing off the elderly with second-rate [illegible] Besides, if the patient enjoyed only a very [illegible] range of activity before the accident, he cannot afford to lose any of it. On the other hand treatment must not be too academic. Thus, in general it is a sound rule not to allow weight-bearing in a fractured femur after pinning until the bone has united; but this delay can render an old person bedridden.

Another reason often given for refusing proper treatment is that the patients occupy much-needed beds for a long time, and may never recover sufficiently to leave. Yet if they are left untreated, they take a very long time to die. They are not, as is so often stated, overwhelmed by hypostatic pneumonia; they linger on for months in a state of suspended but noisy animation. Of the last 50 inpatients (over the age of 75) whom Flemming had treated for fractures, only 2 failed to return home. The argument that they do not stand an anæsthetic is completely unfounded. A patient has to be far tougher to lead a useful life with a painful unreduced fracture than to withstand the stress of reduction; and patients left with untreated dislocated shoulders and Colles fractures develop nerve palsies.

The commonest fractures in the aged are intertrochanteric and pertrochanteric fractures of the neck of the femur. Flemming advises skeletal traction with a Steinmann's pin through the crest of the tibia; or as an alternative a triflanged nail with vertical plate; this second operation is moderately severe and he reports that the results are no better than with traction, except that the patient can be got out of bed sooner. But he considers that each case has to be judged on its own merits. He emphasises that it is very important to make every effort to return old people to their homes; in general hospital wards, they become noisy and deteriorate mentally and physically. Because fractures of the femoral neck are common in the elderly and because they often fail to unite, it has been quite wrongly assumed that fractures of long bones in the old will not join.

Cosin (1947) thinks that an operation for a fractured femur produces less shock than being bounced on and off a bedpan several times daily and having the bed-linen often changed. He states that immobilisation is a waste of the nurses' time, and causes an increase in joint stiffness, respiratory complications, and venous thrombosis. Many other references are available advising operation and discussing details of technical procedure.

The following case-histories of fractures in patients are instructive:

Case 6.—Mrs. G, aged 80, fractured her femur two years ago; no treatment was carried out. Now both her knees are contracted; she is doubly incontinent and apathetic though she remains sensible; she often declares that she wishes she were dead.

Case 7.—Mrs. H. aged 70, fractured her femur ten years ago; no treatment was given and she was bedridden until 1950. She has no contractures but there is 2 in. shortening of the affected leg. She was gradually mobilised and supplied with a patten to correct the shortening. After one year's hard work, she was walking with assistance.

Case 8.—Mrs. I, aged 78, fractured her femur. and the fracture was plated at once. Two months later she was insisting on walking with a stick, stiffly but unaided.

Case 9.—Mr. J, aged 80, was able to walk short distances in the ward and put on his own clothes. He fell and sustained a Colles fracture of his right wrist. The fracture was not reduced, and, being unable to do anything for himself he became so disgusted with life that he preferred to remain in bed.

Conclusion

The task of rehabilitating old people is never easy, and it is particularly difficult when they have lain neglected in an old "chronic" hospital; but it is most rewarding work. At first the difficulties seem to be insurmountable—the opposition of the diehards, the fears and the conservative attitude of the nurses, the frail physique of the patients, and the unsuitable nature of the traditional "bedridden wards." Only the knowledge of equal difficulties overcome elsewhere, and of the spectacular results achieved, can give the beginner courage to go on. When the first tentative steps are made, progress—if any—is at a snail's pace. The patient is got out of bed for ten minutes and sat in a chair: she slips off in a "wee turn" and has to be hastily tucked in again. Next day she seems stronger, and is more lively and interested: but the examination of her crooked knees gives new cause for despondency. Yet surely the effort is worth while, for at worst she may be taught to get about in a wheel-chair; and at best she can be unbelievably improved by remedial exercises and she can succeed in walking again unaided. The Balkan beam is brought along, bed-end exercises are begun, and a few steps are taken pushing a chair; or else the patient is launched with the help of the walking-machine from which she proceeds to two Warral sticks and then, if we are lucky, to a plain walking-stick with a rubber end. All this work is slow and laborious for patient, nurses, and doctor, and there is little perceptible change each day. But if one looks around the wards a year later—or even sooner—the transformation is startling. The hospital has ceased to be a stronghold of apathy and gloom. The great majority of the patients are out of bed for some part of the day. (In our hospital only 15% of the female patients are now bed-ridden compared with 95% in 1949.)

viously described by Thrower and Campbell to 10 ml of the P V P solution, 0 1 ml of a 0 1 *N* iodine solution in 0 1 *N* potassium iodide is added, and the optical density is measured after 10–15 minutes The concentration of P V P present is found by using experimentally determined calibration curves

The urine, plasma, or serum must be pretreated, as previously described, before the above measurements are made An alternative method of removing proteins by acetic acid [2] has been found satisfactory

A fuller account of this method will be published later

SUPPORTIVE THERAPY

SIR,—I was interested in the Manchester article of Jan 10 describing an improved type of dextran Will someone please tell me why this material is dissolved in physiological saline solution? Has 6% dextran no osmotic pressure at all? I feel that it is almost impertinent to remind you, Sir, that the normal serum chloride level is equivalent to a 0 58% solution of sodium chloride, and that physiological saline contains (usually) 0 9% of sodium chloride, a somewhat unphysiological excess of chloride

BOVINE TUBERCULOSIS AND HUMAN TUBERCULOSIS

SIR,—In reply to Mr Daw (Dec 27) I should like to say that population variations were taken into account in every county mentioned in the figures given in my letter (Dec 6) The increase or decrease in the number of notifications is per 100,000 population Mr Daw states that "something more than an apparent statistical relationship is required before any such hypothesis can be accepted" In my view, when 10 out of the 11 Scottish counties, with more than 50% of cattle attested, show an increase in human pulmonary tuberculosis, and when 10 out of 11 Scottish counties, with less than 16 5% of cattle attested, show a reduction, the one result is the consequence of the one cause

I gave the figures for the 11 Scottish counties with the highest and lowest proportions of attested cattle The 10 counties with proportions between those of these two groups would show no significant alteration

Mr Daw also says "I find Mr Pitcher's argument unconvincing" It has long been assumed that bovine tuberculosis increases human tuberculosis What I have tried to show is that the elimination of bovine tuberculosis does not decrease human infection, but very substantially increases it

Turning to the points raised by Dr Bradshaw (Jan 10), I applied in every case to the county medical officer of health for notifications of pulmonary and non-pulmonary tuberculosis for the years 1920 (before tuberculin testing of cattle) to 1950 (when the attested cattle scheme had been in existence for fourteen years, although tuberculin testing of cattle was being practised to a fairly wide extent before 1936, especially in Scotland) I simply took the average for the first five years and compared it with the average for the last five years, taking into account the number of people notified as having pulmonary tuberculosis In some cases, where figures for the full period were not obtained, the earliest five years were contrasted with the latest five years

The significant feature in Scotland is that until about 1936 all the Scottish counties were showing a reduction in tuberculosis notifications, and this reduction has continued in the counties with relatively few attested cattle, whereas the reverse is taking place in co

with 50% or more of attested cattle

CONGENITAL ANOMALIES OF THE BON THORAX AND LUNGS

SIR,—I have examined miniature fluorograph

18,570 soldiers, aged 22–28, and I have found

following abnormalities of the bony thorax

(1) Supernumerary cervical ribs	31 (0 17%
Bilateral	7 (0 04%
Unilateral (rt sided 18, lt sided 6)	24 (0 13%
(2) Synostosis of ribs	14 (0 07%
Between the 1st and 2nd ribs	12
Between the 1st, 2nd, and 3rd ribs	1
Between the 8th and 9th ribs	1
(3) Rudimentary 1st thoracic ribs	3 (0 02%

There were thus 48 (0 26%) rib anomalies in all

These figures, although they refer to young men

agree quite well with those previously published

None of the 31 men with cervical ribs had any symp

attributable to the condition, though they were all accusto

to strenuous exercise In 12 cases the radial pulse disapp

when the hand was raised above the head and bent towa

the opposite side

Steiner[2] found 6 cases of tuberculosis among 59 people wh

had anomalies of the ribs, but in only 1 of my cases was th tostomies do not figure as operative deaths: they discarded to chronic institutions, still attached the bed by means of tube-and-bottle. They endure existence made wretched by the debilitating effects a chronic urinary infection and the repeated pain bladder washouts and changing of tubes, in an ever- ting smell of heavily infected urine and rubber tubing. eir whole life becomes centred on the wound and the oe; their habits deteriorate; they gradually curl , often under the sheet, and usually die within a year operation. Surely it would be preferable to give such tients a chance of survival, even if it were only a slight e. It is possible to get a few of them up soon after eration with a special belt and bag, and train them to ok after it themselves in a hygienic manner. They ay even go home for a time and have the tube changed a district nurse; though they usually return with mptoms of ascending infection and uræmia.

Obituary

FRANK KEITH HAYMAN

M B Lond., F R C S

Dr Hayman, who died on Jan 9 at his home at Sharnbrook, Bedfordshire, at the age of 59, had spent most of his medical working life at Yarmouth, and he was consulting surgeon to the Great Yarmouth General Hospital

His father and grandfather had both practised dentistry in Bristol, and he was educated at Clifton School and Bristol University He took his M B Lond in 1916 and then served abroad with the R A M C On his return he took the F R C S in 1920, and the following year he settled in Great Yarmouth as a partner in an old-established practice Within five years he was appointed assistant surgeon to the Great Yarmouth General Hospital and he became full surgeon in 1927

L L, a colleague at Yarmouth, writes "Keith Hayman was always cheerful and unassuming, and perhaps his chief characteristic was his equanimity, which in the war rose superior to several bombing attacks in his neighbourhood, and one very large bomb which exploded within a few yards of his house His holidays were spent in a motor-drawn caravan, which he had built himself, for the hands of the surgeon could be adapted at will to another skilled craft"

In 1945 ill health forced Hayman into at any rate semi-retirement After he left Yarmouth he held a Ministry of Pensions appointment until his love of clinical work led him to return to general practice in Bedfordshire

A W A, a friend from schooldays onwards, writes "Keith was notably gifted with his gadgets and always making or acquiring or inventing In sports he excelled at swimming and diving, in the arts he was a keen exponent of the piano Always he was a man of deed not word, and what he wanted he usually effected His independent enterprising character led him to start practice on the East Coast, and medicine there gained, what Bristol has missed, a doctor who sought the precise truth in diagnosis and hated humbug and self-deception He tended his patient with a gentle, kindly, human skill His self-effacing nature accorded with his slight regard for ceremony and convention, and was combined with reliability and an intrepid spirit"

Notes and News

W H O EXECUTIVE BOARD

WHEN the 11th session of the executive board of th Health Organisation opened in Geneva on Jan. 12, t man, Lieut Colonel M Jafar, director general o Pakistan, expressed grave concern at the orga financial position Because of action by the United Technical Assistance Board, he said, "we are to be have already been asked to cut down expenditure existing projects, and reduce them as much as possi future This reduction is bound to have serious Speaking of governments participating in health the chairman said "It would be an impossible p tell them now that W H O cannot meet its c any more The U N Technical Assistance *as we are all aware, was planned to bring in the* international assistance, as against bilateral An ference with it at this stage will mean a reversal of th which has encouraged national governments a great far" The chairman went on to declare that it seem health had been given a back number in the sphere and economic development "If this is the attitu very difficult to understand how development in agr food production, industrialisation, or the availa healthy labour can go ahead without proper develop the field of health" The chairman remarked that very important item on the agenda was the nomina *new director-general to succeed Dr* Brock Chisholm, retiring in July The board is to meet privately on to decide on a nomination for the post, this nom will be placed before the sixth World Health As which opens in Geneva in May

At a later session Dr A T Shousha, director Eastern Mediterranean Region, reported that the committee had been unable to meet since 1950 because political situation, the Arab League had decided th regional meeting at which Israel was represented sho attended by its member governments

SIXTH INTERNATIONAL CONGRESS FOR MICROBIOLOGY

THE first International Congress for Microbiology was in 1930 in Paris The second, planned for Berlin in 1933, to be postponed because of political events, and it was ev ally held in 1936 in London At the outbreak of September, 1939, the third congress took place in New the fourth was in Copenhagen in 1947, and the fifth Rio de Janeiro in 1950 The next congress is to be held year from Sept 6 to 12 in Rome, and the preli *programme has now been issued by the organising*

Membership of the congress is open to "all persons inte in the subject of microbiology" There is a registration of 12,000 lire, or 10,000 lire for members of a scientific soc Registrations should be sent to the secretary of the congre Instituto di Igiene "G Sanarelli," Città Universitaria, Rom before May 31

The congress opens on Sunday, Sept 6, at 10 A M, there be scientific sessions from 8 30 A M to 12 30 P M and 3 30 to 6 6 30 P M each day except Thursday, Sept 10, which is free for an excursion The closing session will be on Saturd Sept 12, at 4 P M, followed by the official banquet (5000 l at 9 P M

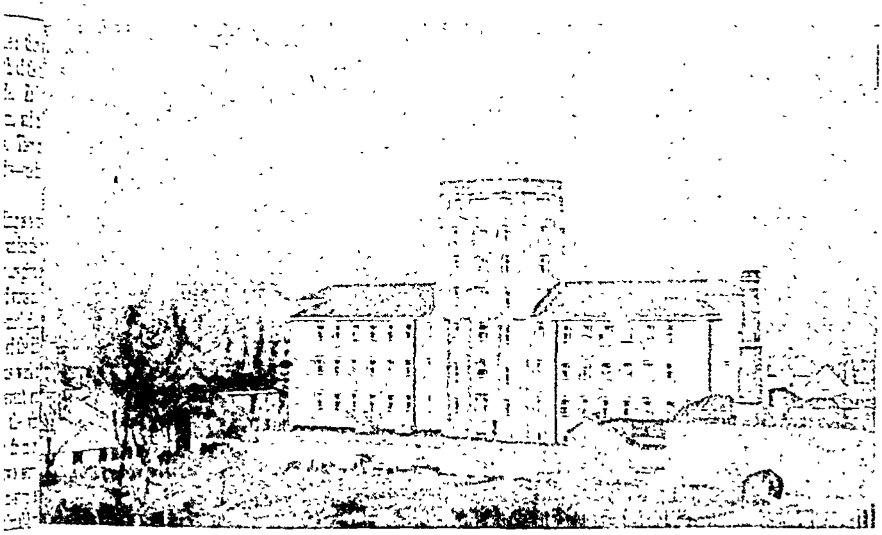
Any member may give a paper to a section, and he sho submit the title and two copies of an abstract (not more th 500 words) to the secretary before April 30 Fifteen min will be allowed for each paper

Lectures by invited speakers will be given on bacte cytology, microbial metabolism, nutrition and growth facto growth inhibitors and chemotherapy, morphology, biol and systematics of the actinomycetales, and host interactions

MEDICINE IN THE SUDAN

THE report of the Sudanese medical services for 19 is an excellent skeleton The bare bones of accomplishme in preventive medicine, in medical education, in research, in the hospitals are shown in 34 tables supported by a factual text

For a population of just under 9 million people there health budget of over £2 million and an established med staff of 1275 people, of whom 116 are British and about



View of the new building.

Dr. Betty Hobbs, while Dr. Patricia Carpenter is in arge of the *Dysentery Reference Laboratory.*

The ground floor houses a number of activities. There a photographic department, some individual research boratories, and a suite of rooms for Dr. W. Charles ckburn's *Epidemiological Research Unit.* Much of the ork of the Public Health Laboratory Service involves idemiological surveys, requiring coöperation with the edical officer of health—for example, the successful ials of whooping-cough vaccine recently carried out ider the direction of the Medical Research Council.

But the new building, though it is by far the largest gle unit of the Central Public Health Laboratory, es not accommodate by any means all of its activities. he work of the laboratory has been severely handipped in the past by lack of space, and the new building ow makes it possible both to rearrange work already eing done and to open up new lines of work. The old ain building will continue to be the headquarters of the irector, Lieut.-Colonel H. J. Bensted. Colindale, in ddition to all its other activities, is also a public-health boratory in its own right and deals with the bacteriology f the surrounding area. The routine laboratory is to emain in this block, together with the *Standards Laboraory for Serological Reagents* under Colonel Bensted's irection. The Standards Laboratory issues diagnostic era and bacterial suspensions and other biological eagents not only to other public-health laboratories ut to hospital laboratories throughout the country.

The old main building still houses the *Central Enteric eference Laboratory and Bureau* directed by Dr. Felix, F.R.S. This is an international as well as a ational laboratory, devoted to the study of methods of dentifying typhoid bacilli, defining new types or subypes, and maintaining a register of known typhoid arriers, besides undertaking research on many of the roblems raised by the method of bacteriophage typing.

In another building is the *National Collection of Type ultures* under the direction of Dr. S. T. Cowan. A large ollection of reference cultures is maintained here, many f them in the dried state, so as to reduce bacterial ariation as far as is possible.

There is another building for the library, suitable also for holding conferences, and others for stores and canteen. There are several separate animal-houses, arranged so as to give the least possible risk of infection and cross-infection.

FUNCTIONS OF THE SERVICE

This in bare summary is an outline of present activities, whose scope will be greatly extended by the completion of the new building. Colindale is quickly becoming one of the main centres in the world in the field of public-health bacteriology and epidemiology. Its reference laboratories are a vital part of the Public Health Laboratory Service, which now possesses, in addition to Colindale, several regional laboratories and 46 area laboratories. From all of these laboratories Colindale receives cultures for precise identification by special methods. The value of these reference laboratories has been proved already in the investigation of numerous outbreaks of different kinds, and many intricate and fascinating epidemics have been unravelled with a speed which would not have been achieved in any other way. It is important to note, too, that this service is not confined to laboratories within the Public Health Laboratory Service. Hospital and other laboratories call upon it for help, and the new accommodation should make possible an increase in this important work.

Though the Public Health Laboratory Service has been described as "about the only section of the National Health Service which receives only *praise and no criticism,*"[1] its many-sided activities are still not as widely known as they should be. It has grown in thirteen years from a small compact organisation of some dozen laboratories to its present outstanding position in preventive medicine. From those modest origins there has been a steady expansion which has culminated in the building now completed. The outstanding success of the service has been due at first to the genius of men like the late Prof. W. W. C. Topley, Dr. W. M. Scott, and Dr. F. Griffith, and in more recent years to the farsighted policy and tireless enthusiasm of its director, Dr. G. S. Wilson, and its chairman, Dr. A. Landsborough Thomson. Under their guidance the service has achieved efficient central direction without sacrificing individuality at the periphery. The new building at Colindale is proof of the initiative and courage of those who have managed in these days of frustration and delay to carry it through to completion.

Congratulations are due to all those who have played a part in this project, and to the architects, Messrs. Maxwell Ayrton & Partners, for a building which combines utility with dignity. Colonel Bensted and his colleagues can look forward to enjoying the use of premises worthy of the high standards which their work demands.

FRIENDS OF THE HOSPITALS

THE voluntary tradition in this country, like the small flame of the lighted touch-paper of a firework display, runs ahead sketching an outline which presently will spring into activity and light. The National League of Hospital Friends is not yet four years old but it has already pointed to many ways in which the lot of patients in hospital can be improved.

At the annual general meeting held at St. Bartholomew's Hospital on Jan. 14, Mr. IAIN MACLEOD, the Minister of Health, could hardly have encouraged the work of the league in stronger terms. He recalled the record of a local league formed in 1948 in Aberystwyth, which decided that the first call on its funds should be a former public-assistance institution for the aged and chronic sick. The first and immediate gift of 20 com-

1. Daley, W. A. *Amer. J. publ. Hlth,* 1952, 42, 1232.

College of General Practitioners

By Jan 15 over 1000 doctors had joined the newly formed college The address of the college is 14, Black Friars Lane, Queen Victoria Street, London, E C 4

British Association of Urological Surgeons

This association's annual meeting is to be held in Leeds on June 25–27 The proceedings are to include a discussion on *Urinary Tuberculosis*, which will be opened by Mr J Cosbie Ross

Laboratory Animals Bureau Congress

The sixth congress of the bureau is to be held at the Royal Veterinary College, London, N W 1, on Friday and Saturday, March 27 and 28 Sir Harold Himsworth, secretary of the Medical Research Council, will give the opening address

Oxford Graduates Medical Club

The winter dinner of this club will be held at the Royal College of Surgeons, Lincoln's Inn Fields, London, W C 2, on Friday, Jan 30, at 7 P M, when Sir Rudolph Peters, F R S, will be in the chair Tickets (30s) may be had from Mr Selwyn Taylor, 3, Roedean Crescent, Roehampton, S W 15

Psychology of Eating

The Scottish group of the Nutrition Society will hold a meeting on Saturday, Jan 31, at 1 20 P M at Marischal College, Aberdeen, when this subject will be discussed The speakers will include Prof W M. Millar, Prof C F W Illingworth, Dr C F Rolland, Dr J M Walker, and Dr C G Kennedy Further particulars may be had from Dr E C Owen, Hannah Dairy Research Institute, Kirkhill, Ayr

King Edward VII's Hospital for Officers

Lieut Colonel Claude Shepherd has compiled, at his own expense, an historical record of the first 50 years of this hospital for Service officers, which was founded by Miss Agnes Keyser during the Boer War Copies (*2s 6d*) may be had from the hospital, Beaumont House, Beaumont Street, London, W 1, and all proceeds will go to the funds of the hospital

French Exchange Scholarships

Under a reciprocal arrangement with the Centre National de la Recherche Scientifique, the Medical Research Council invite applications from British workers in medical science, excluding clinical medicine, for two scholarships tenable at research institutions in France during 1953–54 The stipend of the scholarships will be 45,000–90,000 francs a month, according to qualifications and experience, and married men will receive a supplementary allowance Forms of application may be had from the secretary of the council, 38, Old Queen Street, London, S W 1, with whom applications must be lodged by March 31, 1953

EMERGENCY BED SERVICE —In the week ended last applications for general acute cases numbered 1700 The prop admitted was 83 97%

Dr A W C Bennett, who has been medical officer to the for Great Western Railway and the western region of British Railwa at Swindon for the past 23 years retired on Dec 31

In England Now

unning Commentary by Peripatetic Correspondents

looks as if the long word has had it. The cult of the one. started, or at any rate revived, by the Fowler iers. has had a strong boost in the works of Sir st Gowers, that formidably unprevaricating arch-gonist of antisesquipedalianism. The jet age has ime for arabesques in language or in art, and the que and rococo are gone with the wind.

vay with such useless lumber as adjectives, articles, unctions and prepositions! Let's see the naked ity of the noun, especially the monosyllabic one, ulable in a trice as we and the train we must catch e simultaneously at the station bookstall. Let's our magazine *Life*, *Time*, *Girl*, *Mind*, *Brain*, or *d*. Take for instance that old stage-coach the *ceedings of the Society for Experimental Biology and licine*: dare we suggest *Frog* as a breath-saver? l would the *Journal of Pathology and Bacteriology* template *Death* or entertain *Bugs* as an alternative? *nily Doctor* would soon be out of the red with a title h as *Pep*, *Zip*, or *Zest*, and the *Provincial Medical and gical Journal* might shed its interim guise of *British lical Journal* and appear as *Doc*. Our senior clinical rnals would take a new lease of life under names like e or *Pain*, *Cut* or *Slash*, and *Womb* or *Birth*. To the tro-enterologists we commend *Tripe* or *Guts*, to the sical medicine men *Rub* or *Tap*, and to the rheumatosts *Damp* or *Wet*. The social medicine people may be teful for *Fog*, and the hospital administrators for *pe*.

o far as we can see, the only catch about all this is risk of getting something you don't want, for pubers and detergent makers are running neck and neck. erefore be sure to buy at a bookshop, otherwise you y get soap for the body or its wrappings and not for mind. Don't forget there's a world of difference ween *Time* and *Tide*.

* * *

Five years ago, before coming to Warwickshire, I was ptical of the influence of microclimatology upon ease. A bracing climate meant, I thought, a keen evailing wind, and a relaxing climate a tendency to gs and a still atmosphere, neither of which I believed uld affect more than the psychological health of the sidents. I am now sure that I was wrong and that the health from catarrhal respiratory illness at all ages considerably greater along the Avon valley than it is, r example, in London. It is not so much that infections e more frequent, as that they last longer, and are prone produce complications, such as bronchitis and sinusitis, which the victims are unused in other places. The planation is a riddle. Popularly, damp, fogginess, and "stagnant atmosphere" (whatever that means) are amed, though the humidity of a river valley does not ach that of seaside areas, and there is more particulate atter in London air than there is here. It is not oticeably colder, nor is there so much overcrowding ere as in healthier parts, indeed the reverse, nor are hanges in temperature any more extreme or sudden.

So I think that a purely physical effect of climate on eople is unlikely. After all, mucous membranes cannot e expected to react in very many different ways; they an be chilled or warmed, caused to secrete more or ss, and to become congested or bloodless. There is ttle subtlety in this and we should look elsewhere for he explanation of a general susceptibility, perhaps to the ffect of climate on the growth and virulence of the rganisms that cause our repeated catarrhs. A study of bacterial ecology in relation to the soil and climate of different parts of this island could show that a winter differing from elsewhere by only one or two degrees of average temperature, where the soil contained critical races of certain elements, would provoke luxuriantly malign growth of common pathogens. In other words that the fertile Vale of Evesham is also a bacterial market garden; that not only its fruit and vegetables but equally its micro-organisms flourish exceedingly. And may it not follow from this, knowing the general antagonism between animal and vegetable kingdoms, that for men to be healthy they should seek places where other animals thrive, but that if they choose to live in a vegetable paradise they will become the constant prey of parasitic vegetables?

* * *

"'Ello Luv!" The lady addressing me had attended my outpatient session that morning. The scene of our reunion was the savings bank, where—as a consultant without merit—I do most of my business. As the queue moved slowly up to the counter, I realised more than ever how like the O.P. the bank is. At both, you hand in your book at point A. Your little job needs privacy: you go to point B, a cubicle where you absent-mindedly start to undress. The job done, you are discharged in public at point C. It all takes time—the trajectory described took me a good half hour—and I was attended to by a probationer into the bargain.

Self: "I'd like my interest for the year."

Clerk: "Do you want something out?"

Self: "No! thanks, I just want my interest put in my book. And I'd like some Savings Certificates, please."

Clerk: "What are those?"

Self: "The things the Government keeps asking you to buy."

Clerk: "You'll have to go through that door."

Self: "It's the tenth issue I want; I've got the others."

Clerk: "There isn't a tenth; there's only the ninth."

Self: "The ninth, then. How many can I have?"

Clerk: "Seven hundred."

Self: "The extra ones, I mean. I'll give you a cheque."

Clerk: "Oh no, you have to take it out of what you've got in."

Self: "May I have my book, please?"

Clerk: "You can't have it back here—you have to go through the door to where it says Don't Come on Saturdays."

Discharged at last, I reflected that I had indeed had my interest for the year.

* * *

A friend of ours recently returned from a somewhat trying social weekend spent at a house where they keep a herd of yellow cats for decorative purposes. The doyen of the establishment, a large and cynical tom, had of late taken to looking on the place merely as a sort of second-rate hotel serving indifferent meals. He now lived in the rafters of a disused outhouse, and visited the house at rare intervals, speaking to no-one. It was generally felt that the animal was not pulling its weight, and our friend, stamped as an animal fancier because of his knowledge of the internal economy of the Wistar rat, was deputed to catch the cat and take him to the vet to be destroyed. Physiologists are brave enough in a reckless sort of way, and our friend accepted the commission. Armed only with a cardboard hatbox and his personality, he approached his quarry during its siesta by means of a long ladder. The cat observed the operation dreamily, and such was the lethargy induced by its excesses of the previous night that, after a purely formal protest which caused our friend to fall headlong down four rungs and nearly lost him the sight of one eye, it suffered itself to be placed in the hatbox, secured with string, and settled on the back seat of the car.

By the first traffic lights it had become clear that the cat, though tolerant of hatboxes, thought nothing of cars, and was taking itself to task for allowing itself to be imposed upon. At the second traffic lights our friend looked round in response to a sinister tearing noise and observed a yellow eye regarding him balefully through a jagged hole in the hatbox. Before any steps could be taken, the animal had become fully abreast of the situation and emerged as if propelled by a blasting charge. Our friend tells us that the car became full of cats, thereby causing him to reconsider his views on mammalian parthenogenesis in hatboxes; he counted at least fifteen as they flashed past, upsetting ashtrays, disrupting upholstery, and dismantling armrests. Finally one of the multitude landed squarely on the top of our friend's head and shot out of the driving window, leaving the car empty. By the time he had staunched his shredded scalp and returned home the cat was once more in residence in the outhouse and taking a well-earned nap.

The atmosphere at supper was rather chilly, and our friend's reputation as an animal fancier is now confined to the Wistar rat.

hypertrophy and a little unfolding and calcification of the aortic arch, the skull was normal Nothing abnormal was found in the urine

Fasting blood sugar (F B S) levels of 60 mg per 100 ml were recorded on Oct 7 and 12, 1950, but were not considered low enough to explain her peculiar mental state On Oct 13, 1950, an insulin tolerance test was made with 1 9 units of insulin (a third of the standard intravenous dose) 60 minutes after the injection the patient became unconscious, but she responded quickly when the test was terminated with intravenous glucose Blood sugar levels were F B S 42 mg per 100 ml, 30 minutes after insulin 20 mg per 100 ml, 60 minutes after insulin 26 mg per 100 ml It was only then that we connected her drowsiness and surliness with spontaneous hypoglycæmia, and the insulin-tolerance test would not have been made if we had suspected such a low F B S

On Oct 22, 1950, she became fevered and lost consciousness and was found to have a heavy pyuria Her blood-pressure fell to 64/38 mm Hg but was easily restored Although the blood sugar was not estimated before treatment was started, it was thought that the coma was due to spontaneous hypoglycæmia During the two days she was in coma she lay with rigid limbs and tight jaws and abdominal muscles, her arms flexed at elbow and wrist and crossed on the chest, her knees drawn up and adducted, with extensor plantar reflexes, several flexor spasms occurred The spasticity disappeared when she recovered consciousness For the next few weeks she was in a state of confusional insanity, and there were minimal signs of a left hemiparesis Three months later she had made a complete recovery

Four years after the menopause, pituitary insufficiency came on gradually and for no apparent reason It was thought that spontaneous hypoglycæmia was the cause of intermittent mental confusion, and of a coma which lasted two days, was accompanied by flexed spastic limbs and flexor spasms, and was followed by temporary insanity and temporary neurological abnormalities

Postpartum Lesions

Certain features were common to some or all of the patients of this group all were married women, in cases 3–6 the patients had Sheehan's syndrome, they were bled white in childbirth, and the resultant shock was of appalling severity in cases 3–5, only case 3 had a blood-transfusion, puerperal sepsis ensued in cases 3 and 5, in case 7 the symptoms date from a confinement which may have been complicated by puerperal sepsis but was otherwise normal, this patient has pulmonary and cutaneous tuberculosis

After her last confinement each patient became a different person, afflicted by unaccustomed inertia and frailty Case 4, dull by nature was remarkably free from psychical upsets The others complained of a decline in memory and in powers of concentration, they " couldn't be bothered with anything," and did not want to mix with other people, they were prone to fits of dejection, and pent-up feelings of irritability would explode now and then in little storms of temper The passage of time brought ever increasing slowness of thought and responses, but not peace of mind Cases 3 and 5 often felt anxious and insecure, and case 6 became immersed in terrible waves of gloom and had " awful spells of crying " in a mute submissive way these people seemed grieved by the change in themselves By contrast, case 7 held on to a stubborn grumbling independence in the face of great physical infirmity and the misery of constant family squabbles

All dreaded cold and clung to the fireplace but cases 4 and 5 were relieved of this symptom when they took thyroid extract All spoke of constant tiredness and sleepiness, yet cases 5 and 6 did not sleep well at night Bodily strength waned case 4, the most active, was exhausted on washing days, case 3 had to send the washing to the laundry, cases 5 and 6 became unfit for any household tasks, and case 7 became too feeble to stand Menstruation ceased abruptly except in cases 5 and 7, whose subsequent bleedings are noted in the case reports Libido was lessened in case 4 and lost in the others None had menopausal flushings All lost axillary and pubic hair, cases 3, 4, and 5 recalled that their scalp hair thinned greatly after the delivery and then grew in again Case 3's teeth were extracted before her pregnancy, cases 4, 5, and 6 did not lose the last of their teeth until from five to ten years after the last confinement, and case 7 still had ten decayed stumps I could not obtain accurate information about previous body-weights, cases 3 and 4 lost weight after obstetric shock (case 4 thinks about $3^1/_2$ stone) and regained it in a year or so, cases 5 and 6 grew stouter, but case 5 returned to her usual build when she took thyroid extract Subsequent weight changes were not remarkable, except in case 7, who has tuberculosis and whose appetite was very poor She thinks she weighed 12 stone before her last pregnancy and gradually came down to 6 stone in the next twenty years Cases 3 and 5 did not enjoy their food, case 4 had chronic cholecystitis, the others had no abdominal discomforts, cases 3, 5, and 7 were constipated All complained of breathlessness on exertion, cases 3, 5, 6, and 7 had angina pectoris, and cases 3 and 5 calf claudication Raynaud's phenomena occurred in the fingers of cases 3, 5, and 6 Case 5 complained of transient dizziness on getting out of bed in the mornings, she was the only one who did not have dull headaches Case 7 was troubled by severe leg cramps at night None had urinary symptoms, and all were remarkably free from the common acute respiratory infections

Physical characteristics—Case 4 was dull and unconcerned, whereas case 7 was irritable and hurled enfeebled defiance at her medical attendants, the others were slow gentle people, at once self-pitying and self reproachful, and they rarely smiled Mostly they spoke slowly and quietly, cases 4 and 5 with a little of the thick broken intonation of myxœdema, a contrast to the weak high pitched complaint of case 7 Case 3 was timid and anxious to please, with spare delicate features and a thin weak mouth Case 4, sombre and big-boned, had heavy features and thick lips There was some puffiness of cheeks and eyelids in case 5 The face of case 6 was round and shiny with swelling, and her reddened eyes were sunk in boggy lids, she was utterly miserable and wept silently, without effort Case 7 had a little withered bird like face, with a small receding lower jaw, and a remarkable coarse facial wrinkling made her look old No such impression of senility was given by the others, case 3 actually looked younger than her years in spite of fine facial wrinkling Whatever the facial contours, all seemed curiously fragile, an effect made up of their weakness and unusual pallor The *pallor* was greater than the moderate anæmia would explain, it was spread evenly over the face and, case 6 excepted, it was the more prominent for being unrelieved, it was a milky whiteness in cases 3, 5, and 6, accentuated by the swollen face in case 6 and setting off the red glow on her nose and cheeks, in case 7 it was mixed with grey, in 5 and [illegible] with the faintest tinge of yellow, and in case 4 with a diffuse duskiness A glossy surface to the features of case 5 fused with the even pallor and immobility to simulate a thin wax mask The *buccal mucosa* was swollen greatly in case 6, slightly in case 4, and both had rather big *tongues* *Fat pads* were present above the clavicles of case 6 In case 5 the *skin* seemed a little thinner than normal and was flimsy and transparent over the shins Cutaneous atrophy was not evident in the others, even in case 7, who had an old woman's face but whose skin was elastic and compact on trunk and limbs Apart from the slightest roughness on the fore arms of cases 6 and 7 and on the forearms and shins of case 5, the skin surface was perfectly smooth Only case 4 had a faint diffuse *pigmentation*, probably her natural tint Deeply pigmented *erythema ab igne* covered the lower limbs of cases 4, 6, and 7 (see figure) The rarely come to operation or necropsy, so oppor- s for direct observation are uncommon; but tical considerations are much against his view. area of a roughly elliptical orifice, 1·5 by m., can hardly be greater than 1 sq. cm., and we een that to obtain a cardiac output of only 6 litres inute a pressure gradient across the valve in excess cm. of water is required. This would necessitate siderable rise in left-auricular and pulmonary s and capillary pressures, but catheterisation s of this type of case, with outputs at this level gher), have shown normal pulmonary pressures.[4]

partment of Cardiology,
al Infirmary, Manchester.

GEOFFREY WADE.

BUTAZOLIDINE

—Œdema is not uncommon during treatment with ylbutazone (butazolidine). and there is no need to for swelling of the ankles or face in order to detect f the patient is weighed before and during treatment, ll be found that there is an increase in weight of lb. within two or three days, and as much as lb. at the end of seven to ten days. When the ylbutazone is discontinued, the patient passes us amounts of urine and the weight returns to the nal.

eel that the action of this drug is analgesic rather specific, because pain recurs fairly frequently if njections are more than two to three days apart, t does, in fact, relieve pain in other conditions. For nple. I have observed dramatic relief on two to three sions in severe dysmenorrhœa which had not nded to antispasmodic treatment.

ndon, W.1.

WILLIAM W. FOX.

PINK DISEASE

R,—We were interested in Dr. Vulliamy's [5] suggestion an increase in circulating adrenaline and noradren- might be responsible for the vascular disorder in disease, because we have ourselves been investi- ng this possibility following a suggestion made to us Prof. J. H. Burn in November, 1951.

e have made some preliminary observations on the ary excretion of noradrenaline in normal children and hildren with pink disease; and one of us (G. P. B.) also made studies on adults with proven phæochromo- oma. In each case a 24-hour collection of urine was ained. Noradrenaline was adsorbed on aluminium droxide, and subsequently assayed by intravenous ction into a cat.[6]

he urinary excretion of noradrenaline in 9 convales- t children, whose ages ranged from 3 months to 10 rs, lay between 10 µg. and 27 µg. per 24 hours. In hours the child aged 3 months excreted 18 µg.; and hildren aged 20 months and 2 years excreted 12 µg. 14 µg. 3 adults with proven phæochromocytoma reted 180 µg., 300 µg., and 3700 µg.

o far we have made estimations on only 2 children h Pink disease. Both were classical and fully estab- ed examples of the syndrome, showing prominent rovascular signs—that is to say, hypertension, tachy- dia, sweating, and cold pink puffy hands and feet. affected child excreted 16 µg., and the other 21 µg., adrenaline in 24 hours. These figures lie well within normal range, and contrast sharply with the levels have found in urines from adults with phæochromo- oma. The excretion of noradrenaline fluctuates widely m day to day, and therefore a small average change in retion would be difficult to detect.

he scanty figures that we have so far obtained do support the suggestion that noradrenaline output is greatly increased in pink disease. This does not in any way invalidate the use of 'Priscol' in treatment. Further work is in progress.

CHRONIC OTITIS MEDIA

SIR,—Mr. Layton (Jan. 10) seeks to revive the old idea that the acellular mastoid process is due to sclerotic obliteration of the air cells in a once "normal" pneumatised process. The cases he cites do not support this view: they show merely that inflammation may inhibit further pneumatisation. X-ray examination of the mastoid was practised long before twenty-four years ago when "the first mastoid X-ray picture was taken at the North Eastern Hospital," and since then has been a common procedure. Where is the evidence that a normally pneumatised mastoid (say in a child of 5) ever becomes an acellular or so-called "sclerotic" process? Since hundreds of patients have been radiographed without such a finding we must reject the theory.

E. WATSON-WILLIAMS.

LIGATION OF THE POPLITEAL VEIN

SIR,—Mr. Goligher (Jan. 10) states that the facts recorded in my paper (Jan. 3) do not warrant the conclusion that popliteal ligation is of any value. To refute this conclusion he considers one group only of the recorded cases (those with ulcers) and fails to remark that all of the second group (7 legs), where the patients complained of aching, swelling, &c., of the legs, were relieved of their symptoms.

To return to the group he does consider, he simply states that 7 of the 11 patients showed no sign of recurrence and takes no note of the fact, clearly shown in the paper, that of the cases which failed (5 of 13 legs) 3 should not have been operated upon (in 1 the femoral and popliteal veins were occluded, in 2 there was an arterial deficiency) and were a failure of judgment, not of method; 1 patient refused to wait for a graft but was relieved of her pain and swelling; and 1 ulcer broke down after 2 years. Therefore of the 10 cases which were suitable 8 were successful, 1 partially so despite incomplete treatment, and 1 failed.

Mr. Goligher also "considers that the results are not very different from what might be obtained after bed rest and grafting alone." This, of course, may be so, but such a statement would bear more weight if backed by figures; and it is of interest to note that of 5 cases treated by grafting alone in the Massachusetts General Hospital [1] none remained healed, while of 13 treated by excision of the ulcer and grafting 10 broke down.

The second half of Mr. Goligher's letter concerns the results of superficial femoral vein ligation. He states that "the principle of this operation and that of ligation of the popliteal vein are the same, and the results should presumably be also similar." It might as well be said that because the principle of ligation of the superficial femoral artery and of the popliteal artery are the same, the results should also be similar. Bauer [2] has given the reasons for ligation of the popliteal vein in preference to the superficial femoral; and it is worth noting that Linton [3] has given up ligation of the superficial femoral vein, although he was one of its chief advocates,[1] because of a 30% rate of failure—the same percentage failure as that of Glasser.[4]

I would suggest, then, that Mr. Goligher's failures after superficial femoral vein ligation should not lead him to condemn out of hand ligation of the popliteal vein.

Blood-sugar levels were all estimated by Dr W H R Auld, using the Nelson method He made the *insulin tolerance tests* with a third of the standard intravenous dose in all but case 4, who showed insulin resistance to the full dose

Apart from states of collapse, the levels of *plasma-chlorides, serum-sodium,* and *serum-potassium* were within normal ranges A *fractional test-meal* showed a histamine-fast achlorhydria in case 2, small amounts of free acid after histamine in cases 6 and 7, hypochlorhydria in cases 3 and 5, and normal acidity in case 4 *Hæmoglobin* levels were mildly to moderately depressed (see table) *Stool benzidine* reactions were negative *Peripheral blood smears,* examined in the department of medicine of the University of Aberdeen, showed no macrocytosis Abnormalities in the *chest radiograms* have been mentioned The *pituitary fossa* was radiologically normal in all

DISCUSSION

The nature of the pituitary lesion is not known in 2 cases in case 7, who has tuberculosis of the lungs and skin, the symptoms came on gradually after an easy confinement, which may have been followed by puerperal sepsis, and in case 2 the onset was insidious after the menopause Case 1 had a craniopharyngioma, and in cases 3–6 the illness began abruptly after severe obstetric shock Case 6 recollects pallor and weakness after her first delivery, and recovery of well-being after the second, and it is tempting to postulate a temporary cure of pituitary insufficiency by the second pregnancy (Sheehan and Murdoch 1939) Histological proof of a pituitary lesion was obtained in case 1 In each of the other cases there is reasonable clinical evidence of the presence of a lesion, and only cases 2 and 4 do not satisfy the strict demands for the laboratory diagnosis made by Anderson (1950). low B M R, insulin sensitivity, and hypoglycæmia unresponsiveness, negligible urinary excretion of 17-ketosteroids, and a positive "water test" A Kepler index of over 30 in case 2 can hardly outweigh the rest of the evidence in favour of the diagnosis, case 4 showed some resistance to injected insulin, and part II of the Kepler test yielded a marginal result, but it seems certain that she has an incomplete form of the syndrome, because the symptoms date clearly from appalling obstetric shock, after which she lost her body hair

Clinical recognition of pituitary insufficiency was easy, except perhaps in the postmenopausal case, where some of the symptoms and signs might have been attributed to ageing Nevertheless (apart from infantilism and interference with vision in case 1) the illness *did not conform* to a constant design, and the various pituitary activities were not equally affected, for example, spontaneous hypoglycæmia was calamitous in cases 1 and 2, and moderately severe in case 7, but in the remainder it was absent It seemed, too, that the way in which the patients were altered by the disorder depended not a little on their native mould and temperament Yet 4 of them, including the unconscious dwarf, were left with such a remarkable resemblance to each other that one might have recognised their pituitary insufficiency at a glance These were cases 1, 2, 5, and 6 with the milky skins and puffy faces The first impression of myxœdema was heightened when the eyebrows were sparse, and the correct but incomplete diagnosis of thyroid insufficiency had been made long before in cases 2, 5, and 6 However, these 3 were set apart from the primary myxœdemas by qualities of their own, probably not greatly affected by previous thyroid treatment Patients with severe primary myxœdema, however dulled, often wear a self reliant robustness to match the coarseness of their skin and features, and A Lyall (personal communication) has often been impressed by their dry sense of humour But here the whiteness of the skin was in keeping with the helplessness of case 2 and the sadness and withdrawal of cases 5 and 6, one was aware of an uncanny [illegible] almost as if their hold on life was precarious, one [illegible] worried about these people

The fragility of cases 3 and 7 was less unearthly because it was in harmony with their thin delicate features Case 7 had an old face, but the skin of her body was even and well formed Case 4 was closer in appearance (and in response to injected insulin) to the primary myxœdemas She was dull, almost unconcerned and her features were heavy, but much of all this was inborn, as were the thick lips and faint duskiness of the skin There was an unexpected feebleness about her big frame

The main findings in cases 2–7 are in close keeping with the account of Sheehan and Summers (1949), who selected for review only those patients who were proved to have gross destructive lesions of the anterior lobe of the pituitary A few minor points of disagreement with these workers may be explained by incompleteness of the pituitary lesions Sheehan and Summers (1949) emphasise the lack of localised cutaneous pigmentation, but the erythema ab igne on the legs of cases 4, 6, and 7 was of a deep brownish-black tint (see figure), and case 2 showed dark staining at the site of old varicose dermatitis, the breast areolæ of cases 2 and 4 were deeply pigmented, and they were of a light fawn colour in the remainder—only the dwarf could be said to have had no areolar pigmentation Sheehan and Summers (1949) always found a lack of the normal capillary flush in the exposed skin, very atrophic breast parenchyma, and advanced atrophy of the vagina and external genitalia Case 6, however, had a red nose and red cheeks, and flushed deeply in response to vasodilator substances, there seemed, on palpation, to be abundant breast parenchyma in cases 2 and 7, and vaginal stenosis was absent in cases 3–6 despite superinvolution of the uterus

The *erythrocyte sedimentation rate* (Westergren) was increased in cases 2–7 (see table) Case 4 had chronic cholecystitis, and case 7 old fibroid pulmonary tuberculosis, but in the remainder the increase was not explained

Teeth —In case 1 an excellent set of teeth had not been marred by lack of pituitary hormones There was no clear evidence that the pituitary lesion had led to loss of teeth in the other cases, and this is in keeping with the opinion of Sheehan and Summers (1949)

Myxœdematous swellings have been described in the faces of cases 1, 2, 5, and 6, and were seen in the form of pads above the clavicles in case 6, and in swelling of the oral mucosa and of the tongue in cases 4 and 6 The texture of the skin may have been influenced by previous thyroid treatment in cases 2, 4, 5, and 6 The speech of cases 4 and 5 suggested myxœdema

Arterial disease —There is a high incidence of the effects of arterial disease cases 3, 5, 6, and 7 had angina pectoris, and case 3 has had a myocardial infarction and cases 3 and 6 complain of intermittent claudication in the calves The angina pectoris of case [illegible] was greatly aggravated whenever thyroid extract was prescribed

Adrenal cortical insufficiency —Case 7 had much asthenia and was observed in three attacks of collapse simulating addisonian crises One of these was precipitated by the diarrhœa which followed an aperient, and another by thrombophlebitis The arterial hypotension of cases 1 and 2, when they were first seen in coma, may have been due to concomitant adrenal cortical insufficiency, but blood-pressures were quickly restored by treatment The selective sparing of some pituitary functions is seen again in the lack of any tendency to adrenal crises in cases 3, 4, 5, and 6, and it is of interest in this connection that cases 4 and 5 had taken thyroid extract for long periods, because thyroid has been held responsible for the development of acute adrenal insufficiency in several patients (Cook et al 1951) operation or any line of treatment which ignores this extensive incompetence is not likely to be uniformly sful in healing leg ulcers. Mr. Cockett and Mr. Elgan agree that their follow-up is short, allowing of no e conclusions about the efficiency of their operation, venture to suggest that its basic premise is untenable.

constant finding in phlebograms of ulcerated legs, of column of unsupported blood in the deep veins due to most total absence of valves, led Bauer and others to igate the effect of ligature of the popliteal or superficial But as Mr. Goligher has pointed out (Jan. 10), the s of this operation are equivocal. This is not surprising the column of blood is not a static phenomenon, and a ng valve will hardly be improved if a complete block aced across it. The deep veins are the main channels which blood returns to the heart from the lower limbs, he swelling which follows the operation is ample witness e further rise in venous pressure caused by it. Rest bandaging are even more constantly required than ever.

seems an inescapable conclusion that a reduction enous pressure (and hence healing of the ulcer) can be brought about by restoration of the valvular on in the muscle pump. (In animals an attempt been made to insert acrylic-resin valves, or grafts healthy vein with valve.) Such a restoration can be cted by the simple manœuvre of firm bandaging n toes to knee. Its very simplicity is regarded as ject by a few, but it does in fact appear to provide rm of valvular action within the deep veins. Originally consistently advocated by Mr. Dickson Wright,[1] it y far the most successful form of treatment yet ised, even in the presence of enormous ulcers. It bably acts in this way:

he successive turns of the bandage apply a slightly ying pressure along the leg. Although the surgeon tries ut the bandage on evenly, he never can achieve theoretical ality of pressure throughout, as the faint ridges on the skin icate when the bandage is removed. This "even" pressure uces the average calibre of the vein and the slight variations lude the deep vein at intervals along its length, the rage pressure applied being very little greater than the stolic pressure in that vein. In systole the muscle pump ces blood both up and down the limb through the occluded ments, but mainly upwards, as the resistance is greater tally. In diastole once more, the various points of lusion due to the turns of bandaging prevent regurgitation wnwards of the blood forced upwards during systole.

This valvular action is imperfect but hydrostatically ost effective. The muscle pump has been repaired d venous pressure falls. Inevitably the ulcer heals.

Hampstead General
Hospital, N.W.3.

GERARD KRAFFT.

SIR,—I should like to join in congratulating Mr. ckett and Mr. Elgan Jones on their work on the ankle blow-out syndrome," which is clearly of ndamental importance both in the ætiology and eatment of certain leg ulcers.

The following quotation from John Hilton[2] seems an teresting prelude to the careful anatomical investigaons of Cockett and Elgan Jones:

"Why is it that varicose ulcers occur so frequently at e inner and lower part of the leg? It might be said that ey occur because the blood in the veins of the lower tremities has to run up-hill, and gravitation interferes very uch with the return of the blood; the valves get broken own, and the whole pressure is retrograde, if we may so term , and so these ulcers arise. If that were the sole reason, lcers should occur by preference on the feet or on the toes, ecause these are more remote from the general circulation an the ordinary site of ulcers from varicose veins. Hence, I spect that this cannot be the explanation. The explanation as always—at least for some time past—appeared to me to e this: The superficial and deep veins of the leg freely ommunicate with each other in the neighbourhood of the nkle-joint. The first two inches above that point is the spot here the greatest stress is laid upon these superficial veins; below that point they freely communicate, and if the blood cannot return by the superficial veins, it can do so by the deep veins, or vice versa; but when you reach the point above the inner malleolus (where that brown patch of skin so often occurs in old persons) it is otherwise, and that appears to me to be the reason why ulcers from varicose veins occur so frequently about that neighbourhood."

S. T. ANNING.

COLORIMETRIC ESTIMATION OF POLYVINYLPYRROLIDONE BY IODINE

SIR,—Recent experimental work has enabled us to increase the sensitivity of the colorimetric method for estimating polyvinylpyrrolidone (P.V.P.) described by Thrower and Campbell.[1] The reaction has now been shown to involve free iodine and not the I_3^- ion as previously stated, and consequently, with solutions of iodine in aqueous potassium iodide, the intensity of colour developed depends on the concentration of free iodine, which is governed by the equilibrium

$$I_2 + I^- \rightleftharpoons I_3^-.$$

It is not possible to increase the sensitivity by the use of alcoholic solutions of iodine, in which all the iodine is present in an un-ionised form, since ethyl alcohol interferes with the colour reaction. The behaviour of this coloured complex between iodine and P.V.P. is very similar to that with starch. Thus the colour of the complex is completely discharged by sodium thiosulphate, sodium arsenite, or a strong base. On warming, the colour of the complex disappears but it reappears on cooling.

The observations described here were made at 500 mμ with a Unicam SP 500 spectrophotometer and cells of optical path length 1 cm., but similar results have been obtained with an Eel colorimeter (Ilford 603 filter). The optical densities are measured against an aqueous solution of identical iodine and potassium-iodide concentrations without any P.V.P. All concentrations referred to below are the actual concentrations in the solution being measured.

At constant potassium iodide and iodine concentrations the relationship between optical density and P.V.P. concentration is not a straight line but may approximate to this over a useful range of P.V.P. concentrations at low potassium-iodide and high iodine concentrations. Typical sensitivities in these straight line regions are given in the accompanying table (I, II, III). In addition the maximum sensitivity obtained under conditions similar to those described by Thrower and Campbell[1] are given (IV).

VARIATION OF SENSITIVITY WITH COMPOSITION OF REAGENT

—	Iodine conc. normality	Potassium iodide conc. normality	Sensitivity P.V.P. conc. (mg. per ml.) to give an optical density of 0·05	Useful range of P.V.P. conc. (mg. per ml.)	—
I	$5{\cdot}0 \times 10^{-4}$	$1{\cdot}0 \times 10^{-3}$	0·005	0–0·02	Poor straight line
II	$1{\cdot}0 \times 10^{-3}$	$2{\cdot}0 \times 10^{-3}$	0·0035	0–0·04*	Good straight line
III	$5{\cdot}0 \times 10^{-3}$	$25{\cdot}0 \times 10^{-3}$	0·0022	0–0·03*	Good straight line
IV	$1{\cdot}0 \times 10^{-3}$	150×10^{-3}	0·0175	0–0·425*	No straight line

* The useful range is limited by the inaccuracy of measurement above an optical density of about 0·7.

A further increase in sensitivity by increasing the iodine concentration is impracticable since the blank absorbs too much light. It is found that, with the most sensitive conditions, a considerable time (1–2 hours) is required for the maximum colour to develop, so that it is convenient to sacrifice some sensitivity for greater speed.

These results have suggested the following method, which is about five times more sensitive than that pre-

---

1. Wright, A. D. *Lancet*, 1931, i, 457.

Walker rat carcinoma 256 as well as a depressive influence on the myeloid series both in the rat and in man at a much lower dose than most other members of the series

Table I shows the relation between dose and inhibition of the growth of the Walker carcinoma for all members of the series from $n = 2$ to $n = 10$, here + indicates that the weight of tumour tissue in the treated groups (each of 10 rats) was 10% or less than that of the controls after two or three weeks' growth, the drug being administered in a single intraperitoneal dose twenty-four hours after implantation The activity was greatest with $n = 4$ and $n = 5$, and diminished towards either end of the series

TABLE I—ACTION OF MEMBERS OF THE SERIES ON GROWTH OF WALKER RAT CARCINOMA 256
(Each experiment based upon 10 rats)

Dose (mg per rat of average weight 200 g)	n								
	2	3	4	5	6	7	8	9	10
2	−	−	+	+	+	−	−	−	−
5	−	−			+	+	+	−	−
10	−	+						+	−

Table II, which is taken from the report of an investigation of the effects of this series on the blood by Elson and Timmis summarises briefly the main depressant action on circulating neutrophils in rats This action having been clearly established both in man and in rats, a clinical trial of 1 4-dimethanesulphonyloxybutane, which had already been started, was concentrated on cases of chronic myeloid leukæmia, with results which are described in the accompanying paper by Dr D A G Galton At the same time comparison of myleran with X rays (Elson 1951) and with the reported effects of the nitrogen mustards shows that, unlike these agents, it does not appreciably depress lymphocyte formation at a dose which causes a 50% or more decrease in the number of neutrophils

TABLE II—ACTION OF MEMBERS OF THE SERIES ON CIRCULATING NEUTROPHILS IN RATS

n	Dose (D) (mg per kg of body-weight)	Decrease (%) in no of neutrophils from normal 5–12 days after injection (F)	$\frac{F}{D}$
2	200	0	0
3	40	50	1 3
4	8	70	8 8
5	12	85	7 1
6	40	60	1 5
7	60	40	0 7
8	80	50	0 6
9	100	40	0 4
10	300	0	0

The relatively selective qualities shown by myleran are perhaps reflected in the lack of side effects which is one of its desirable features in clinical use

During clinical trials at the Royal Cancer Hospital and other centres, the code number GT 41 has been used to denote this compound

All these investigations were supported by grants to the Chester Beatty Research Institute from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund, and the National Cancer Institute of the National Institutes of Health, U S Public Health Service

MYLERAN IN CHRONIC MYELOID LEUKÆMIA

RESULTS OF TREATMENT

D A G GALTON
M A , M B Camb
HON CLINICAL ASSISTANT, ROYAL CANCER HOSPITAL, LON

THIS paper reports the results of two years' t of 'Myleran' (1 4-dimethanesulphonyloxybutane) chronic myeloid leukæmia The rationale for the us this substance is explained in the accompanying pa by Prof A Haddow and Mr G M Timmis

DOSAGE AND ANCILLARY TREATMENT

Myleran was given orally in 2 mg tablets Two d schedules were used (1) *courses of 4–10 mg d* lasting 4–16 weeks during which 200–500 mg was giv and (2) one or more short courses in which 100–150 m was given in 1–6 days *Attempts at maintenance thera* with 4–6 mg daily for 1–12 months were made in se cases A modification of the first schedule is now favou in which daily doses of 4 mg are given as long hæmatological improvement continues

Most of the patients were treated in hospital for t first few weeks, but, when repeated small does myleran are used, treatment in hospital is often unnec sary, provided that weekly blood-counts are d Symptomatic treatment was given as required, but o two patients (cases 5 and 9) received blood transfu

Illustrative Case-records

Seven cases of acute leukæmia (five myeloid, c lymphoblastic, and one monocytic) did not respond myleran and are omitted from this report

Of the nineteen patients with chronic myeloid le kæmia seven had not received any previous treatme and twelve had been treated previously by other metho

NO PREVIOUS TREATMENT

Five patients (cases 5, 14, and 17–19) were referred trial of myleran They would otherwise have recei radiotherapy Two other patients (cases 7 and 9) wou have been given treatment other than radiotherapy ev if myleran had not been available, because the leukæm was considered too acute in case 7 and because of t hæmorrhagic state in case 9

Case 5 —A married woman, aged 71, was admitted Feb 15, 1951, with *3 weeks' history of pain of sudden on* over the left lower ribs

On examination she was thin, with pale mucosæ, and grossly enlarged firm spleen, over the upper part of wh friction was palpable and audible The soft edge of the liv was felt at the level of the umbilicus A capillary fragil test (Hess) was positive A blood count on Feb 16 show Hb 10 7 g per 100 ml , white cells 91,400 per c mm. (*neutr* phils 66,265 per c mm , immature myeloid cells* 15,538 p c mm)

Treatment and progress—The patient was given myler 10 mg daily on Feb 17 and 18, and 20 mg daily from Feb to March 4, 1951, to the total of 300 mg in 16 days H spleen and liver regressed rapidly, and her pain ceased S was discharged on Feb 20, 1951, but from March 22 to April 1951, she had repeated severe epistaxis, and multiple purpu spots appeared on her limbs Her Hb decreased rapidly 7 5 g per 100 ml , but the lowest recorded platelet count w 100,000 per c mm, on March 21, 1951 She was readmitt on March 22, 1951, and received a transfusion of six pints fresh blood *No further hæmorrhage took place after April* 1951 From then until she was last seen on Oct 16, 1952, sl has remained extremely fit Her spleen has been only ju palpable on inspiration since October, 1951, and *no immatu* leucocytes have been seen in blood films since April 1, 195 On Oct 16, 1952, her Hb was 17 5 g per 100 ml , and l idence of pulmonary tuberculosis, and the disease was tensive. Another soldier with a rudimentary 1st thoracic o had pulmonary tuberculosis.

E MEDICAL SERVICES IN THE KOREAN WAR

R,—Your article last week on this subject will, in ral, have given satisfaction to all interested in war ery.

was, however, disturbing to note that, while the Forces had ample supplies of fresh blood for trans-on, the Commonwealth Forces were relying mainly lasma. It was the opinion of almost all who worked he forward areas in the Western Desert, Sicily, Italy, North-west Europe that in the treatment of battle alties plasma was good but whole blood was very h better. It is stated that the terrain in Korea is lar to that of Tunisia. At the battles of Mareth and idaville the number of bottles of blood used per 100 alties outnumbered that of plasma by more than to one.[5]

he difficulties of supply of blood in forward areas are siderable; but it is not easy to understand why at was thought desirable, and moreover possible, in 3 does not hold good today.

ove. REX BINNING.

MORE FOOD

SIR,—"Your 1947 Correspondent" when he says "I d you so." (Dec. 13, 1952) is, of course, right in pressing more home food production. But surely he is wrong in cognate arguments? Firstly we cannot forgo any rt of our exports: on the contrary we need more ports to pay for our raw materials, our consumer goods, d our armaments. We need more exports and more me-produced foods. Secondly there can be no panacea nply by allowing the "scale of rewards to the farmer go on swinging up and up."

Many factors are involved in increased food production improved farming skill, dissemination of scientific owledge, improved soil fertility, increased scientific owledge, attraction of skilled farmers back to the hill rms, and cultivation of unused acres. All these cannot achieved simply by higher rewards. Industry has own that monetary reward alone is not a sufficient centive for human endeavour, and it is difficult to agine any reward that would attract a farmer to work arginal land when he can till fertile land instead. The pital outlay needed to convert marginal land into roductive farms requires large-scale investment: only ith the aid of something in the nature of a Home evelopment Corporation could any private individual ontemplate taking over.

It is a fact that many farmers could fairly easily nprove their output and so their profits by the application of scientific methods already practised by the more fficient farmers, yet they will not. Extra profit is not ffective in their case. Similarly, money alone will not attract farmers to the hills; they require the amenities of a civilised life as well.

On the other hand, I agree with your correspondent that farmers should be treated as a special and even privileged class. It is true that many people and political parties are not willing to allow anybody more than a "fair" reward; but would anyone grudge the coal-miner special rewards for doing a difficult and dangerous job that is so essential yet no-one else will do? Under conditions of national emergency we willingly treat our special categories on a privileged basis; and, in regard to food, we are in a world emergency.

We are moving into a period when the world food shortage will soon begin to affect us. At present two-thirds of the world are starving, including countries which export food to us. What will happen when the countries not only eat the food that they now export but even compete with us in the world market for available food?

There is no single solution to this problem. We must develop the underfed countries to help them to feed themselves; we must develop the unused territories; and we must grow more food at home. There is no single method of increasing food production at home; every practical proposal must be followed up—whether it is utilisation of leaf protein, fertilisation of the sea, development of marginal lands, increasing soil fertility, or really collecting all waste food to feed pigs and poultry.

There is an aspect of food prices of special interest to medical men and nutritionists. How can we persuade people to drink more milk and eat more eggs if the prices are high? They prefer to spend their money on films and cigarettes. Are subsidies, or is education, the answer? Or something else? I do not know; but at least I have indicated that your correspondent's panacea of more profit simply cannot work.

London, W.13. A. E. BENDER.

PARONYCHIA

SIR,—Mr. Lowden, whose paper you published last week, seems to have obtained some very good results in this infection, by combining systemic penicillin with locally applied chloramphenicol. This is interesting in view of the reported antagonism between these two antibiotics.[1] The series treated by Mr. Lowden with penicillin alone seems somewhat small for comparison, and no details of dosage are given. It would be interesting to know whether the bacteria isolated in this series were sensitive to penicillin and chloramphenicol together.

On theoretical grounds it might be more desirable to use a local application containing penicillin and streptomycin (of which there is a convenient proprietary preparation), as these two antibiotics are synergistic. It is unlikely that streptomycin resistance would be evoked during the short time of treatment; and the preparation is probably cheaper than the equivalent chloramphenicol one.

In general practice over the past five years I have not encountered any case of paronychia which did not respond to systemic penicillin alone, administered by methods described elsewhere.[2,3] However, my cases are nearly all early ones, as compared with the more extensive cases described by Mr. Lowden in hospital practice. It is probable that many more cases are successfully treated in general practice than reach the hospital casualty department. It might be instructive to hear something of the results obtained by general practitioners in this and allied pyogenic conditions, with regard especially to the periods of disability.

myeloid cells 65,660) per c mm (myeloblasts 3%), and platelets 286,000 per c mm Iliac bone marrow was highly cellular, with the characteristic picture of chronic myeloid leukæmia A capillary fragility test was negative

Treatment and progress—Myleran 10 mg daily was given from Feb 2 to Feb 26, 1951 (total 250 mg in 25 days) and 4 mg daily from May 27, 1951, to April 8, 1952 The patient improved rapidly, became afebrile by Feb 27, 1951, and was fully ambulant by March 7, 1951 Her spleen regressed steadily during the next year and could not be felt after April 8, 1952. A blood count on Feb 12, 1952, showed Hb 12 9 g per 100 ml and white cells 12,500 (neutrophils 11,125, immature myeloid cells 125) per c mm (no myeloblasts or premyelocytes) Iliac bone marrow on March 13, 1951, showed much decreased cellularity, with great relative increase in numbers of erythropoietic elements Sternal marrow on Nov 6, 1951, was of normal cellularity, and the differential count was within normal limits She was in excellent health on May 21, 1952, but was readmitted on July 24 with 3 weeks' history of progressive weakness Her spleen was again grossly enlarged A blood count showed Hb 5 6 g per 100 ml and white cells 64,200 (neutrophils 14,024, immature myeloid cells 49,500) per c mm She died on Sept 19, without responding to further treatment with myleran

Case 11—*A married woman, aged 50, was admitted on* May 19, 1951, with gross swelling of the abdomen, weakness, dyspnœa on exertion, and attacks of spontaneous bruising of the limbs The symptoms had increased in severity since their onset in October, 1949, when chronic myeloid leukæmia was diagnosed Radiotherapy of the spleen was given, but treatment was interrupted because of purpura Several blood transfusions were given but no further radiotherapy

On examination the patient was thin and somewhat pale A fading bruise was present on her right shin, and her abdomen was grossly distended, her umbilicus being everted and stretched The lower edge of her enormous spleen was below the level of both inguinal ligaments and the symphysis pubis The right border was within 3 cm of the right anterior superior iliac spine Her liver was 10 cm below the right costal margin in the midclavicular line A capillary fragility test was negative A blood count on May 29, 1951, showed Hb 6 0 g per 100 ml and white cells 430,000 (neutrophils 199,950, immature myeloid cells 187,050) per c mm (myeloblasts 7%)

Progress and treatment—Myleran 20 mg daily was given from May 25 to May 29, 1951, 4 mg daily from May 30 to July 14, 50 mg daily on July 15 and 16, 25 mg on July 18, and 6 mg daily from July 19 to Aug 29 (total 661 mg in 96 days) Progress was rapid In 3 weeks the patient was free from symptoms, but her spleen, though no longer uncomfortable, was still very large She was fit and active 12 months later A blood count on July 3, 1951, showed Hb 12 4 g per 100 ml and white cells 16,400 (neutrophils 9348, immature myeloid cells 2706) per c mm (no myeloblasts) Splenic regression continued until Nov 30, 1951, when the lower border was 15 cm above the level of the symphysis pubis, and the right border 5 cm to the left of the midline A blood count on Jan 8, 1952, showed Hb 14 4 g per 100 ml and white cells 10,000 (neutrophils 5930, immature myeloid cells 1050) per c mm (no myeloblasts) On June 17, 1952, the patient was in excellent health, but her spleen was rather larger and her liver, which had been impalpable since 1951, was again felt She complained of tiredness and of bruising When she was seen on July 28, her spleen was grossly enlarged and a blood-count showed Hb 9 3 g per 100 ml and white cells 92,000 (neutrophils 42,000, immature myeloid cells 32,000) per c mm A second course of myleran was begun on Sept 29, 1952 The patient responded as before, and when she was last seen on Nov. 4, her spleen was smaller and a blood count showed Hb 13 8 g per 100 ml and white cells 16,600 (immature myeloid cells 4540) per c mm (no myeloblasts)

Thus ten of the nineteen patients were treated as "trial" cases with myleran instead of with X rays, and nine received myleran because radiotherapy was contra indicated or was deemed useless

Review of Results

The results are summarised in the accompanying table, but features of particular interest are considered here in more detail

Symptomatic Relief

The common symptoms were those referable to and to splenic enlargement with its complications perisplenitis and infarction Night sweats and rhagic symptoms were also common In the ten successfully treated patients symptoms were relieved and the patients returned to their normal activity or employment The initial symptomatic response, however, was also satisfactory in the seven patients who relapsed quickly, five of them within 2 months [illegible] of general symptoms sometimes took place abruptly and was evident before any significant increase in Hb (in cases 8 and 9 even while the Hb was decreasing) it was always associated with rapidly falling leucocyte counts when these had been quickly rising before treatment

Splenic Regression

Splenic regression was variable but never less than might have been expected after radiotherapy, and was sometimes better than it had been after radiotherapy previously given Even grossly enlarged spleens became impalpable, this was particularly striking in one patient (case 4), who had already had eleven courses of radiotherapy The spleen remained impalpable for 6–12 months after treatment in cases 4, 7, 14, 15, and 16 Splenic regression was rapid when large doses of myleran were used, but with repeated small doses it often continued slowly for several months.

Hæmatological Changes

Leucocytes—Myleran led to granulopenia in every case The onset was rapid (8 days) with large single doses (100–150 mg) but with repeated small doses was often delayed to 21 days after the first dose The leucocyte count fell steeply with the large doses to reach normal levels in about 4 weeks but with repeated small doses the count fell more gradually for as many months The lymphocytes were affected inconstantly and never significantly Immature myeloid cells were affected sooner and more drastically than were mature neutrophils and in eight cases disappeared altogether for several months, in *case 5 they have not returned 21 months after treatment*

Hæmoglobin—Of all the effects of myleran therapy, that with the greatest prognostic significance is the increase of Hb The average increase in the first 12 weeks was 5 g per 100 ml in the eleven patients whose remissions exceeded 5 months, but in the remainder it was less than 2 g per 100 ml The Hb before treatment was less than 6 5 g per 100 ml in four of the nine most successfully treated patients, and in them the gain in the first 12 weeks after treatment was 4–7 g per 100 ml In several cases the Hb continued to increase after 12 weeks, and the highest levels were reached in an average of 23 weeks (longest 38$^1/_2$ weeks in case 3, shortest 13$^1/_2$ weeks in case 14) The highest level varied from 12 2 g per 100 ml in case 3 to 17 5 g in case 5, but only one of the seven patients whose remissions lasted less than 5 months achieved 12 6 g Blood transfusion was required in only one (case 5) of the nine successfully treated patients, this was for a transient hæmorrhagic phase a month after treatment with large doses of myleran which induced thrombocytopenia

Reticulocytes—Regular changes in the reticulocyte count during treatment were noted in some cases in which reticulocyte levels were below 1% before treatment, the count rose to a peak (up to 17 2% in case 19) between the 3rd and 5th weeks and then fell to pre treatment levels

Bone marrow—Estimates of bone marrow cellularity that are based on aspiration films are unreliable, but gross changes observed repeatedly after treatment are probably significant Comparison of samples taken at the time of the lowest leucocyte count with those taken before treatment showed that the aspirates were markedly hypocellular, erythropoiesis was relatively more con

During the year there were 303,000 admissions to l, and 31,000 operations were performed. There was a epidemic of meningococcal meningitis with 57,000 Over 350,000 patients were treated for malaria, and ly 25,000 a blood film proved positive. In the Gezira d area some 17% of the population are infected with somiasis. There are 35 students in the Kitchener of Medicine. Over 38,000 routine bacteriological and ical tests were carried out.

e real achievements are set out so briefly and with so omment that only a reader experienced in tropical ne will grasp that the Sudanese people have the benefit nall but efficient and progressive medical service. For dinary reader the report lacks flesh and blood. In the today exciting battles are being fought against malaria, gococcal meningitis, schistosomiasis, tuberculosis, mal- ion, and maternal ignorance. Could not next year's describe some of the highlights of the campaigns in ige which all can understand? Some pictures would is to appreciate the work. The work is of interest aportance to us all today, when departments of African aments are liable to fall suddenly within the searchlight rld opinion. And proper judgments for future policies aly be formed if educated people, both in Africa and in orld outside, know something about African technical ems.'

ART FROM MENTAL HOSPITALS

r May an exhibition of amateur paintings organised by ociety for Education in Art included a large section ed to entries from mental hospitals; and a collection of ngs and sculptures by psychiatric patients is at present exhibited at the Geffrye Museum, Kingsland Road, on, and will remain on view until Feb. 1. Among the ures, a moving series of fourteen carvings depicting ay to the Cross were previously shown at the S.E.A. ition. These are the work of a young woman patient—fessional artist—at Netherne Hospital, Coulsdon. The ngs are from Leavesden Hospital, where art-therapy ns have been held weekly for nine months. Many of the ats whose work is shown are mental defectives with al ages from about nine years downwards (on scale I e Wechsler-Bellevue intelligence test); but the speech me of them was so poor that they could not be tested. ame as a surprise," according to a note in the catalogue, discover that many of these patients were capable of taneous activity. They really enjoyed the painting ons—the mere application of colour to paper had its t upon them." The note adds that much of their initial essness and uncertainty of conduct disappeared while were painting.

ae National Association for Mental Health have set up a ommittee which, during the past year, has been inquiring the position of art-therapy in mental hospitals, its aims functions, and the qualifications desirable in those who tise it. Doctors have long recognised that a patient's tings may reflect the progress of his illness remarkably ifully—sombre colouring and subjects giving place to ier tones and more cheerful themes, for instance, as he es out of a depression and regains his normal mood. Art nental hospitals has thus been regarded as contributing iagnosis, rather than as a form of therapy; yet it almost ainly has therapeutic value too. An interim memorandum ining some of the difficulties and complexities of the ject has been prepared and presented to the main com- tee of the association, but has not yet been made public.

CENTENARY IN BAVARIA

N the first half of the 19th century Bavarian doctors an to feel a need for greater cohesion and opportunity for ring experience. Accordingly, in 1833 twenty doctors up the Münich Medical Society. Several attempts publish regularly a Bavarian medical journal ended in are; but at the end of 1852 Dr. Alois Martin, probably ired by Hermann Oettinger, announced his intention of ading another such journal, and after some delay the first e appeared on Jan. 7, 1854, under the title *Aerztliches elligenzblatt: Organ für Bayerns staatliche und öffentliche lkunde*. Martin retired in 1869. In 1885 Bernhard Spatz k over the appointment, and in 1886 the title was changed *Münchener Medizinische Wochenschrift*. The change was nore than the title; for under Spatz's wise leadership the nal increased its scope and became known and read by ny beyond the range of Bavaria. In the jubilee issue of the journal (Jan. 2, 1953) G. B. Gruber recalls that in its time it has published much well-known original work. Between 1944 and 1950 publication was suspended; but, as Gruber shows, the circulation is rapidly climbing back towards the 1944 peak of 18,000. Dr. Hans Spatz, the son of Bernhard Spatz, now shares the editorship with Prof. Georg Landes.

JOURNAL OF EMBRYOLOGY AND EXPERIMENTAL MORPHOLOGY

AN editorial board has lately been at work preparing the way for a new quarterly journal, the *Journal of Embryology and Experimental Morphology*. The first issue is planned for the coming spring. The editorial board, a strong international team, has decided that the scope of the new journal shall include "work on embryogenesis, growth, and developmental processes in the older organism as well as studies on fœtal-maternal relationships." Most articles will be in English, though some in French and German will also be included. The editor is Mr. M. Abercrombie, M.A., reader in embryology in the University of London. Prof. J. Z. Young, F.R.S., is chairman of the editorial board, and Mr. D. R. Newth, PH.D., lecturer in the department of zoology, University College, London, is its secretary.

University of Cambridge

On Dec. 23 the following degrees were conferred by proxy:

M.B., B.Chir.—C. W. M. Adams, L. P. Balfour-Lynn, W. M. Beatley, M. H. Bennett, D. W. K. Bird, G. M. P. Boyes, D. A. P. Burton, W. H. Chapman, H. S. Chen, R. C. Curry, S. H. Dallas, Aileen B. Donnison, J. A. Fiddian, S. J. Fisher, D. B. Fox, Hanna French, A. M. B. Golding, R. K. Greenwood, J. M. S. Grieve, A. N. Griffith, H. F. Grundy, R. D. Hernaman-Johnson, M. D. Heyman, Vera M. C. B. P. Hollyhock, B. L. Hoskyns, B. S. Jay, H. E. Lichtenstein, I. S. Lister, Gillian G. Matthews, P. L. Maybury, R. L. Morgan, K. F. Morrice, T. M. O. Morris, M. T. O'Donnell, E. M. Orton, J. T. H. Pick, J. F. Preece, P. M. H. Rack, Frederic Reisceger, T. L. Ringrose, R. D. W. Romanis, W. A. G. Roper, C. S. Savage, T. L. Scully, E. P. Simkin, I. F. Smith, I. A. Stewart, G. D. Stones, L. J. Stretton, M. C. Thornton, D. S. Trouton, J. A. M. Tudor-Hart, Ruth M. Turner, A. E. Wagstaff, H. C. M. Walton, A. W. Warltier, P. A. Watt, Ian Weinbren, F. L. Whalley, W. G. Williams, J. O. Winter.

Dr. A. D. Gardner, F.R.C.P., regius professor of medicine in the University of Oxford, will deliver the Rede lecture in the Senate House, at 5 P.M., on Thursday, May 14. He will speak on the Proper Study of Mankind.

University of London

Prof. P. Mallet-Guy of the department of surgical pathology, University of Lyons, will deliver a lecture at St. Mary's Hospital Medical School, Paddington, W.2, at 5 P.M. on Thursday, March 5. He will speak in French on Les Opérations Sympathiques dans le Traitement des Pancréatites Chroniques Récidivantes.

University of Sheffield

On June 26 the honorary degree of D.SC. will be conferred on Sir Ernest Finch, formerly professor of surgery in the university.

Scottish Society of Anæsthetists

The annual meeting of this society will be held at Dunblane Hotel Hydro from the evening of Friday, April 24, until Sunday, April 26, under the presidency of Dr. W. M. Shearer. Dr. I. W. Magill will be a guest of the society.

Liverpool Medical Exhibition

On Monday, May 18, at 11.30 A.M., Dr. E. Noble Chamberlain will open this exhibition at St. George's Hall, Liverpool. Only doctors will be admitted, and the exhibition will be open daily from 11 A.M. to 6.30 P.M. until May 22.

Institute of Psychiatry, London

On Monday, Feb. 2, at 8 P.M., at this institute at the Maudsley Hospital, Denmark Hill, S.E.5, Prof. Konrad Lorenz (Max Planck Institute, Buldern, Westphalia), will deliver a lecture on Comparative Psychology and Psychiatry. On Feb. 6, at 3 P.M., Prof. H. C. Rümke (Utrecht) will give a lecture on the Clinical Significance of Obsessional Phenomena.

Conference on World Health

The United Nations Student Association is holding a conference on this subject on Saturday, Feb. 7, at 2.15 P.M., at 16, Queen Anne's Gate, London, S.W.1. The speakers will include Dr. Neville Goodman, Dr. Harold Balme, and Dr. C. H. Andrewes, F.R.S. Further particulars may be had from UNSA, 25, Charles Street, W.1.

during the terminal pancytopenic phase, was predominantly myeloblastic

Platelets —The platelet count fell somewhat in all the patients treated, especially in those who received the larger doses of myleran The fall continued longer than that of the granular leucocytes, and the lowest counts were recorded 13–21 weeks after the first dose of myleran Hæmorrhagic states necessitated blood-transfusion in cases 5 and 13

Resistance to Myleran

The leucocyte count fell in every patient treated with myleran for the first time In cases 6, 10, and 12 subsequently rising counts did not respond or were arrested for only a few days, although doses of myleran several times larger than were necessary to bring about the initial fall in leucocyte-count were given In cases 10 and 12 all the circulating granulocytes shared this rapidly acquired resistance to myleran, but in case 6 the mature neutrophils responded as they had at first, and the rising counts were made up largely of dwarf undifferentiated hyperchromatic blast-cells It is perhaps significant that these three patients received large doses initially

Side effects of Myleran

No patient complained of any symptom that could be attributed to myleran Three patients (cases 3, 11, and 14) developed diffuse brownish pigmentation of the face, forearms chest, and abdomen during treatment, this wore off during the next three months In case 1, when repeated blood-transfusions were given during the terminal phase, the more intense and widespread pigmentation characteristic of hæmosiderosis appeared Agranulocytosis is due to overdose, but thrombocytopenia may develop with therapeutic doses, particularly when large doses are used or when the platelet-count is much below 100,000 per c mm when treatment is begun Myleran therapy therefore requires constant hæmatological supervision Weekly estimations of hæmoglobin total and differential leucocyte counts, and platelet-counts are necessary during the critical phases of treatment, when rapid changes are taking place

Discussion

Radiotherapy is the best palliative treatment in chronic myeloid leukæmia that has stood the test of time It can induce repeated remissions for as long as 12 years, although most cases enter the resistant phases in less than half this time (Ledlie 1953) Its disadvantages are (1) that radiation sickness sometimes accompanies it, though much less often than formerly, (2) that splenic regression lessens with the later courses and the symptoms resulting from chronic splenomegaly are no longer relieved and may be further aggravated by perisplenitis caused by X rays, and (3) that treatment must be given at specially equipped centres In spite of these disadvantages no other palliative treatment has taken the place of radiotherapy, although several drugs are useful, especially in areas remote from radiotherapy centres, or when radiotherapy has lost its efficacy The best-known drugs are arsenite (as *Fowler's solution*), benzene, urethane, nitrogen mustard, and such recent modifications as 2-naphthyldi 2′ chloroethylamine and 2 4 6 tri-ethylene-imino-1 3 5-triazine Radioactive phosphorus should be regarded as a form of radiotherapy Drug-induced remissions are usually short lived, compared with those brought about by radiotherapy, and side-effects are often objectionable Radioactive phosphorus requires specialised equipment, must be handled by skilled personnel, and has no advantages over X rays 2 4 6 tri-ethylene imino-1 3 5 triazine has few side-effects, but its performance is inferior to that of radiotherapy (Karnofsky et al 1951, Paterson and Boland 1951, Silverberg and Dameshek 1952)

If a new palliative remedy is to compete successfully with radiotherapy it must be as efficacious and it must be safe, free from undesirable side effects, and easy administer If it is to take the place of other must improve on their performance in patients for radiotherapy is contra-indicated An essential feature radiotherapy is that it can induce remissions rep In considering the claims of myleran to a place in peutics, it is emphasised that little is yet known of its action on relapse following prolonged first remission

The severity of disease represented in this small ranges from that of the very chronic case, with few symptoms, which might have responded equally well any of the recognised treatments, to that of rapid advancing disease which had already responded poor to them Some patients were treated for the first time and others had already been treated, in some cases repeatedly, by other methods, to which they were becoming more or less refractory With this wide range of clinical types it is not surprising that the response to myleran varied accordingly, and that some patients were extremely sensitive to myleran and obtained dramatic and prolonged remissions, whereas others responded poorly and relapsed quickly It is therefore difficult to give more than a preliminary and tentative assessment of myleran Except in three cases the results were no worse than those which might have been expected with any other form of treatment, and in at least seven cases they were similar to the best of which any other method is capable Five of the nine patients who were regarded as unlikely to obtain any further benefit from radiotherapy nevertheless obtained useful, and in four cases outstandingly successful, remissions with myleran The three exceptions include cases 6 and 12, who acquired resistance to myleran, and case 13, whose bone marrow failed 4 months after treatment These three had all received large doses of myleran, which are consequently considered dangerous, although several of the most successfully treated patients tolerated these large doses without mishap (cases 3, 5, 7, 11, and 14)

Even if later experience fails to confirm the present impression that myleran is superior to other drugs in respect of the extent of splenic regression, the length of remissions, and the rapidity and completeness with which symptoms are relieved, myleran will still have the advantages of simplicity of administration, absence of side effects, and occasional effectiveness after other methods have had to be abandoned

Any benefit which patients with chronic myeloid leukæmia derive from myleran probably results solely from the removal of the ill effects of excessive myelopoiesis for it is unlikely that myleran's action depends on anything more specific than its ability to depress granulopoiesis In non-leukæmic people single doses of 2 mg per kg of body-weight depress the monocyte and neutrophil counts and sometimes the platelet count, but lymphocytes are irregularly and inconstantly affected In therapeutic doses myleran acts preferentially on myelopoiesis, but this apparent selectivity is only relative Large doses may have contributed to the terminal failure of erythropoiesis in cases 1, 3, 6, and 12 The non specificity of action of myleran is well shown by its failure to induce remission in acute leukæmia, chronic myeloid leukæmia in acute myeloblastic relapse, and myelofibrosis, where disturbed myelopoiesis is merely incidental to some more fundamental upset and is not a major cause of the symptoms

The preliminary results described here are nevertheless encouraging, and myleran clearly merits further trial in cases for which radiotherapy would ordinarily be given as well as in cases where radiotherapy is considered to hold out no chance of further palliation

Summary

1 4 Dimethanesulphonyloxybutane (myleran) was given orally to nineteen patients with chronic myeloid leukæmia In therapeutic doses myleran depressed

TUITARY INSUFFICIENCY IN WOMEN

A CLINICAL STUDY OF SEVEN CASES

L. A. WILSON
M.A., M.B. Aberd., M.R.C.P.
OR MEDICAL REGISTRAR, ABERDEEN ROYAL INFIRMARY

> "... that whiter skin of hers than snow,
> And smooth as monumental alabaster."—*Othello*.

E find sometimes that rare diseases become strangely mon after we have learnt how to recognise them ; , ever since Sheehan (1939) dealt so lucidly with the tetric lesions, it has been known that pituitary defects far from rare. Defective function of the anterior of the pituitary gland is now the subject of much arch, and it is not surprising that this is being sued in the laboratory more than at the bedside ; for ny excellent clinical descriptions, particularly that of ehan and Summers (1949), leave little for others to If something remains to be added, it is because uitary mischief varies so much in its extent and effects, l the portrayal of another 7 selected female cases y illustrate the manysidedness of the syndrome. I ve not attempted a general picture of pituitary ufficiency, because writings on this topic are volumi- us, and we are fortunate in having the comprehensive iews of Sheehan and Summers (1949), Farquharson 50), and Perkins and Rynearson (1952).

I have followed Perkins and Rynearson in preferring term "pituitary insufficiency," if only because it ls a little easier on the tongue than "hypopituitarism," anhypopituitarism," "hypoantuitarism," "anterior popituitarism," and "hypo-anterior-pituitarism." Simmonds's disease" is a well-worn term, but the unds of its meaning are ill-defined. This objection does t apply to "Sheehan's syndrome," which is used below mean pituitary insufficiency after obstetric shock.

Sheehan and Summers (1949) and Perkins and ynearson (1952) do not deal with dwarfism, but I have cluded a pituitary dwarf in this series to emphasise at cases of pituitary insufficiency with onset in childood need not differ in some important aspects from ases with onset in adult life.

THE PATIENTS

The patients have been observed in the past three and half years. According to the likely time of onset, the ituitary defects are classified as prepuberal (case 1), ostmenopausal (case 2), and postpartum (cases 3–7). ome general and laboratory data of cases 2–7 are given n the accompanying table ; case 1 is not included, ecause the patient was admitted in coma and few of hese data were obtained. Treatment and progress are ot discussed but are mentioned briefly when indispensable to the clinical description.

Prepuberal Lesion

Case 1.—A spinster, aged 39, whose first symptom was loss of the sight of the right eye at the age of 12 years, retained a juvenile appearance and stature, did not menstruate, and disliked cold. Examinations in other hospitals in 1936 and 1945 revealed right optic atrophy, left temporal visual field defect, and pituitary dwarfism ; and there were radiological signs of a pituitary tumour whose calcified capsule was seen to extend intracranially. She had been bright and intelligent, but after October, 1950, was often mentally deranged. On Oct. 20, 1951, she vomited and thereafter became confused and incontinent, and had cold sweats, and little nourishment seems to have been given while she was in this state.

On admission on Oct. 31, 1951, she was deeply unconscious, and her blood-pressure was unrecordable. She was small and somewhat plump, looking about 15 years old ; her face was puffy and remarkably pale ; her Hb was 82% (Haldane). Her skin was a little rough on her limbs but smooth elsewhere ; there was healed psoriasis of the elbows. Her scalp hair was profuse and dry, eyebrows scanty, axillæ hairless but greasy, pubic hair absent, and hairs on the vulva scanty and dark. There was no palpable breast tissue ; the nipples were tiny ; and the areolæ were tiny and devoid of pigment. Bilateral optic atrophy was present. The limbs were flaccid, becoming rigid in extension later that day, with extensor plantar reflexes. Tightly clenched jaws prevented close inspection of the teeth, but they appeared strong, white, even, and flawless except for a few metal fillings.

Blood was removed for sugar estimation, and intravenous dextrose was given. Ventriculograms done two hours later by Mr. W. Martin Nichols showed no ventricular shift or dilatation. Meanwhile we learnt that the blood-sugar on admission was 3 mg. per 100 ml. (Nelson method). The blood-sugar level and blood-pressure were promptly restored and maintained, and intensive treatment included the use of cortisone acetate, but the patient did not recover consciousness. She lay in a state resembling decerebrate rigidity, with fixed jaws and firm abdominal muscles, spastic extended limbs, and extensor plantar reflexes ; her arms were adducted and fully rotated inwards, and her hands were clenched ; and her feet became rigidly inverted. There were frequent tonic spasms, with arching of the back. Bronchopneumonia and purulent stomatitis appeared early, and it was astonishing that she did not die until thirty-one days after admission.

Necropsy findings (Dr. A. Wynn Williams).—There was a large cystic suprasellar craniopharyngioma, 3 cm. in diameter, associated with softening of the cerebral tissues for 3–4 mm. around its upper margin ; the sella had been destroyed and no normal pituitary tissue was found. There was considerable hypoplasia of the various organs and tissues, particularly the other endocrine glands and the genitalia. Bronchopneumonia and ulcers in mouth were found. The teeth were healthy.

The immediate clinical problem was to find out if the large pituitary tumour had caused unconsciousness from intracranial pressure effects ; but the ventriculograms did not show any internal hydrocephalus. Spontaneous hypoglycæmia was also considered, and its presence was confirmed by a blood-sugar level of 3 mg. per 100 ml. Since the subsequent necropsy findings did not indicate that the tumour had caused any significant pressure on the brain stem, it seems very likely that spontaneous hypoglycæmia was indeed responsible for the mental derangements of the previous year, and for the terminal coma with its peculiar neurological accompaniments. Unfortunately it was impossible to revive a patient whose blood and brain had been starved of glucose for some eleven days before treatment was started. Even so, it is worthy of note that this pituitary dwarf survived to the end of the fourth decade, and that she retained her juvenile appearance.

Postmenopausal Lesion

Case 2.—A married woman, aged 64, had been subject, since the age of 16, to epileptic fits preceded by bitemporal headache and vomiting. She had borne two children normally in 1910 and 1913, and each baby was at the breast for six months. Menstruation ceased in 1936, when she was 50. Strong, energetic, and quick-witted until 1940, she was then slowly afflicted by weakness, listlessness, depression, anorexia, and dread of cold. Her daughters described a shuffling gait, thinning eyebrows, and a pale swollen face, so different from her former sharp features and dimpled chin. She took thyroid extract irregularly and without benefit. She ate little during a head-cold in January, 1950, and was drowsy and muddled ; after this she was often confused in the afternoons or during the night. Her appetite failed and she lost flesh. She complained of severe pain and stiffness in the knees.

On admission on Oct. 2, 1950, she was weak, sluggish, miserable, muddled, and peevish. She was well nourished. Her skin was milky pale and exceedingly smooth, her face puffy and finely wrinkled. Her scalp hair was thinning a little but of good texture ; she had sparse eyebrows, scanty lower eyelashes, and only a few axillary and pubic hairs. Breasts, nipples, and areolæ appeared normal. Her abdominal muscles were firmly contracted. Knee movements caused pain and palpable grating. She had a slight dorsal kyphosis. The skin of her legs was pigmented from healed dermatitis associated with varicose veins. A few lens opacities and moderate retinal arteriosclerosis were discovered ; the visual fields were later found to be full. Radiography showed some left ventricular patient could have projected delusional ideas, exaggerated or prevaricated *An interview with the wife and an investigation* by the psychiatric social worker revealed that the essence of the wife's reports was true, though she tended to give highly coloured versions, and also that there was some basis for the patient's allegations, though these were much exaggerated.

Rarely it may happen that a fact and a delusional statement made by a patient agree by sheer accident This does not make the statement less delusional, for the psychiatrist, *in such a case, is concerned more with the manner* in which the patient arrives at his belief than with the belief itself For example, a paranoid patient asserts that he is persecuted by a person whom he has never met, and further imputes a certain bad trait to that person's character, it may well happen that the person in question does exhibit such a trait, but this does not make the accusation any the less delusional, since it was derived from paranoid thinking, not from factual observation.

Some of the delusional statements of a patient may be factually true—and a consequence of his abnormal behaviour A paranoid schizophrenic who behaves in an odd, eccentric manner will surely be remarked upon or pointed out, and this will confirm his original feelings that he was being watched Neighbours are not always patient with the divagations of a psychotic and may retaliate against his abuse or aggression—which is then quoted by him as proof of the neighbour's persecutory activities

Very rare indeed must be an instance where fate arranges so that delusions are neatly confirmed by reality An excellent example is given by Dostoievsky in *The Friend of the Family* Tatyana Ivanovna imagined that rich, elegant suitors were paying court to her

She was already on the borderline of a psychosis when, as Dostoievsky puts it, destiny played a last fatal jest at her expense'—she inherited immense wealth. And now indeed dozens of real suitors began to pay her ardent attentions, and the lady was too deluded to realise that it was her money they were really after Had she consulted a psychiatrist at this stage and told him that she was pestered by many men, he would hardly have been able to assess her complaint as delusional He might indeed have doubted the motivations of the suitors, but would have found it very difficult to prove or disprove whether they were driven by love (as the patient believed) or by cupidity (as was the fact)

A reality situation which plays into the hands of the psychotic's delusions need not, however, prevent his recovery In Pirandello's *Henry IV* the environment had been altered to conform with the psychotic's delusions; when the hero recovered his sanity, he turned the tables, and decided (because it suited him) to play up to the environment, and pretend to be insane Here a psychiatrist would have been hard put to it to disentangle pretence from delusion

Though the mere harbouring of a delusion does not matter, provided behaviour is not disturbed in a person leading a tolerable social life, yet it can be of vital importance to diagnose after a patient has been certified and detained in a mental hospital In certain paranoid states, where delusions are limited in relation to some one person or a particular situation, the patient can be a model of good behaviour in the hospital, and to make matters more difficult he may minimise or completely deny delusions he had previously expressed, in order to obtain his discharge

Case 2 —A married man aged 67 was admitted because he had made a suicidal attempt, and because he threatened to kill his wife (12 years younger), alleging that she was having an affair with a neighbour The evidence he gave of her alleged infidelity was circumstantial and unconvincing, but he managed to persuade a newly appointed house physician, who recorded He may be unduly jealous but it is not entirely certain that his suspicions have not been supported by fact" The patient was perfectly well behaved and soon made light of his delusions He was discharged, but had to be readmitted after only two months, having aga his wife's life intolerable by his threats and repeated d accusations Again he settled down as a model of in the hospital, enjoying the amenities of extended Subsequently he was discharged to the care of a br promising not to return to his wife

HELPFUL CRITERIA

The presence of other symptoms of mental illness example, depression, apathy, elation, or hallucinat *will support the likelihood that* the patient's sta are delusional, if these fit into a recognised c pattern. But difficulties arise in the type of ca other symptoms are absent, or so slightly beyond variation as not to be conclusive Careful, detail tioning may reveal that the "factual evidence" pr by the patient to substantiate the veracity of hi are too vague, wild, or bizarre for acceptance

Case 3 —A married man aged 64 was admitted after having threatened to kill his second wife, alleg had been unfaithful He had divorced his first wi infidelity and his second wife was nearly 25 years h so there was a suitable situation for an attitude of However, the type of evidence he produced was not con ing He said that he heard noises downstairs, and wh descended he found his wife alone but the back of h was covered with dog's hair He came to the co that she must have been lying on the floor on h *obviously for sexual purposes*

Fortunately we do not have to rely merely on feasibility of the patient's statements we can obtain some guidance by studying his manner of pre tation or his reactions to the alleged insults The pa patient over-protests his probity, innocence, or exhibits a self-righteous attitude, and readily be heated in forcibly insisting upon the justice of h arguments Generalisations such as "jealousy of o —tongues of other people make mischief—libel a slander," are often repeated, but somehow one ca track down specific incidents that could be investig and confirmed Allegations are accompanied by self-justifications as "I keep myself to myself—I like mind my own business and expect others to do the —I don't like gossip" Colourful, exaggerated phr may be used

Case 4.—A paranoid epileptic who had been disch to the care of her husband *ranted as follows* "My husb has been mean, cruel, brutal—he is a filthy beast an gluttonous skunk—eighteen years of my married life h been torture—I must have justice—I will show the w by God I will—he was let free whilst I had to suff because the solicitor and doctor wouldn't do their w properly—do you wonder why the country is in such a s and so on

In contrast I would quote a case where it was felt th the allegations were not delusional Here the pati was calm, able to reason, and could see both sides of th problem

Case 5 —A male outpatient aged 45 was referred f claustrophobia He found his clerical work in an o a great strain and sometimes he made errors in his accou for which he had been reprimanded He suspects, howev that an ambitious younger man had "fiddled" his accou with the result that he (the patient) was reduced in rank Th injury he believes was motivated because some time pr viously he had reported certain improprieties of that empl to the manager A verbatim report of part of the inter best illustrates how the rational mind works

Doctor Could you prove to the satisfaction of a co of law that this other person had played about with yo accounts?

Patient No It would be my word against his

Doctor Perhaps you did make the errors in ques yourself—as you admit you sometimes did

Patient I generally ferreted them out myself and th made the necessary corrections

Doctor But perhaps not all of them

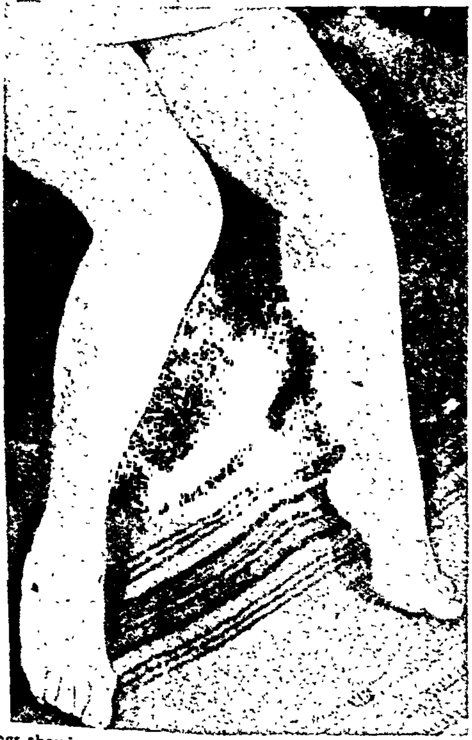
ls of case 4 were brittle ; those of cases 3, 5, 6, and 7 wed longitudinal ridging, and those of cases 5, 6, and howed terminal curving. The scalp *hair* was healthy, ring some thinness in case 7, dryness in cases 4 and 6, l early greying in cases 5, 6, and 7. Case 5 had normal ebrows, but those of the others were thinned, particu- ly in the outer halves. The lower eyelashes of cases 3 d 7 were scanty. Fine down could be seen on minute pection of face and limbs. Axillary and pubic hair re absent or nearly so. Although the *breast* contours emed normal, hardly any mammary tissue could be t in cases 3, 4, and 6, and very little in case 5 ; but se 7 had a good allowance of glandular breast substance. e breast areolæ were deeply pigmented in case 4 and ht brown in the rest. Case 4 had big, and the others all, nipples. On *vaginal examination* the body of the erus was not palpable and the cervix could barely be lt as a tiny nodule. The vagina was atrophied in case 7 t admitted two fingers in the others. Cases 3 and 4 d small internal *hæmorrhoids*, which had not produced mptoms. The *thyroid glands* were not palpable. ases 4, 5, and 7 showed a slight *dorsal kyphosis*. Early *inal arteriosclerosis* was recorded in cases 5 and 6. *utrition* was fair in case 7 and normal in case 3 ; and ses 4, 5, and 6 were fat.

There follows additional information about individual atients.

Case 3 had had angina pectoris for three years. Since coming der observation she has complained of intermittent claudi- tion in the calves and has had a myocardial infarction.

Case 4.—Tuberculous neck glands were dissected in 1940. had been prescribed regularly since 1947 ; epiness, cold intolerance, and Raynaud's he fingers, but did not restore energy and infected gall-bladder was removed recently.

Case 5.—In 1919 she had severe influenza. A retained piece f placenta was removed five days after the postpartum æmorrhage in 1926, and she was dangerously ill with puerperal septicæmia " for the next three months. She had wo further vaginal bleedings, both heavy, before the meno- ause in 1928. She took thyroid extract regularly after 1928 ; it " made life worth living " after the intense misery of the previous two years, and relieved intolerance of cold ; but it did not bring back strength. She had angina pectoris and intermittent claudication. There were systolic cardiac murmurs ; the popliteal and ankle pulses were absent. There were scars on the legs from ulcers in childhood.



Legs showing deeply pigmented erythema ab igne in case 6.

GENERAL DATA AND SOME LABORATORY INVESTIGATIONS IN CASES 2–7

Case no.		2	3	4	5	6	7
Age (yr.)		64	45	48	55	46	49
No. of children born ..		2	1	3	3	3	5

Blood Wassermann reaction		Neg.	Neg.	Neg.	Neg.	Neg.	Neg.

Case 6.—Her memory is poor, but she thinks she bled heavily with each of her three confinements ; after the first she was pale and weak, but felt stronger after the second. Thyroid extract was prescribed about the time of onset of her angina pectoris a year before admission, but it so aggravated the cardiac pain that she became afraid of the drug and took it only rarely. X rays showed considerable expansion of the aortic arch. The blood-plasma was laden with fat. The skin flushed deeply in response to inhalations of amyl nitrite and injections of nicotinic acid.

Case 7.—She was ill for three weeks after her last delivery with a " poisoned stomach." She was pitifully feeble, complained grievously of cold, and whined if disturbed. Her face was little and wizened, her lower jaw small and receding, her palate low and flat ; and her tongue narrow, red, and pointed. Her hands were unusually small, and her arms short and thin. Despite her loss of weight she had a fair covering of subcutaneous fat. Both optic discs showed slight temporal pallor, of doubtful import ; the visual fields were full. A solitary nodule of lupus vulgaris was present on the nasal skin. The left hip was stiff, and the left leg short.

Radiography revealed old-standing fibroid tuberculosis of the upper zones of both lungs ; the left femoral head was flattened, apparently from old osteochondritis ; no calcification was seen in the adrenals.

On Dec. 5, 1951, a dose of laxative was followed by diarrhœa and profound circulatory collapse, with hypochloræmia and moderate hypoglycæmia. Later she had an attack of spontaneous hypoglycæmia ; and two other episodes of circulatory collapse occurred, one preceded by unexplained diarrhœa, the other by thrombophlebitis.

SPECIAL INVESTIGATIONS

Many special investigations were made, but only pertinent ones relating to cases 2–7 are mentioned. Some results are shown in the table.

Basal metabolic rates (B.M.R.) were estimated by Dr. A. Lyall or by Dr. W. Bowman by gas analysis of specimens collected in Douglas bags. Case 5 was taking thyroid 2 g. daily at the time ; case 2 may have taken thyroid extract until a week before the estimation ; case 4 had had none for four weeks.

Urinary 17-ketosteroids were assayed by Dr. W. Bowman, who used Callow's method in cases 2–6, and the M.R.C. standard method in case 7. Excretions were negligible.

Kepler test.—Part I was positive in all. In cases 2 and 4 part II was negative, but a repeat test in case 4 gave an index of 23.

Storage Temperatures

Samples were kept either at −79°C or at −20°C The lower temperature was maintained in a tank containing a mixture of solid carbon dioxide and alcohol, the tank itself being surrounded by large blocks of solid carbon dioxide within an insulated box Although an attempt was made to keep the alcohol bath continuously supplied with chipped carbon dioxide, in practice this was not always achieved, and the temperature of the alcohol was sometimes as high as −70°C for several hours at a time

A temperature of approximately −20°C was maintained in an ordinary deep-freeze cabinet, in which the temperature varied between approximately −17°C and −22°C

Percentage Hæmolysis

The percentage hæmolysis in a sample was calculated as follows

The hæmoglobin concentrations of the supernatant (Hb_s) and of the whole sample (Hb_W) were determined in a photoelectric colorimeter using an Ilford 625 filter Percentage hæmolysis was then expressed as

$$\frac{Hb_s \times \frac{100 - P\,C\,V}{100}}{Hb_W} \times 100,$$

P C V being the packed cell volume of the whole sample

RESULTS

Glycerol Concentration and Optimum Rate of Freezing

Using the 15% glycerol-saline solution described by Sloviter (1951), it was noted that for blood frozen to −79°C in bulk (500 ml) the mere process of freezing and thawing often resulted *in as much as 10–20%* hæmolysis On the other hand, small samples (2–5 ml) showed much less hæmolysis, and it was suspected that the more rapid freezing and thawing attainable with the small volumes of blood was responsible for the discrepancy

In attempting to find a means of diminishing the hæmolysis occurring during the freezing and thawing of large volumes of blood, the effect of a range of glycerol concentrations (2 5–30%) was investigated, using blood-glycerol mixtures sealed into capillary tubes of approximately 1 mm bore It was found that when freezing was rapid (about 3 seconds), hæmolysis occurred in all the glycerol concentrations used, however, the degree of lysis varied, amounting to only about 30% in glycerol concentrations of 8–10%, compared with almost 100% in glycerol concentrations of 15–30% For slower freezing (between 15 and 100 seconds), glycerol concentrations of 15–30% were optimal, and concentrations below 15% showed distinctly more hæmolysis It was concluded that hæmolysis during freezing and thawing was determined to some extent by the relation of glycerol concentration to the rate of freezing, and that higher glycerol concentrations (20–30%) would be more suitable for large quantities of blood.

Independent studies by Lovelock (1953) confirmed the desirability of using a higher concentration of glycerol for freezing to −79°C His work also suggested that lowering the final plasma concentration of sodium chloride from 0 15 *M* to 0 12 *M* would further enhance the value of using the higher glycerol concentration Accordingly, bottles containing 420 ml of blood, mixed with 120 ml of the standard acid citrate dextrose solution and stored at 4°C for not more than 7 days, were prepared for freezing by removing 240 ml of citrated plasma and replacing it by 200 ml of a mixture of 50% glycerol and 0 425% sodium chloride solution Such bottles were frozen to −79°C by one of two methods

(1) Plunging them directly into a CO_2 alcohol bath, when solidification was complete in 15–20 minutes

(2) Rotating the bottles in a CO_2 alcohol bath, using the mechanical roller device described by Mollison and Sloviter (1951), when solidification was complete in 8–10 minutes

As had been anticipated, hæmolysis was slight in all bottles, and did not in fact exceed 5% in any instance Evidently with large volumes of blood, containing relatively high concentrations of glycerol, rapid f unnecessary

Some bottles of blood frozen in this way and at −79°C showed less than 5% hæmolysis after 2

Rate of Hæmolysis of Red Cells Stored in Different Ve at −20°C (Test-tube experiments)

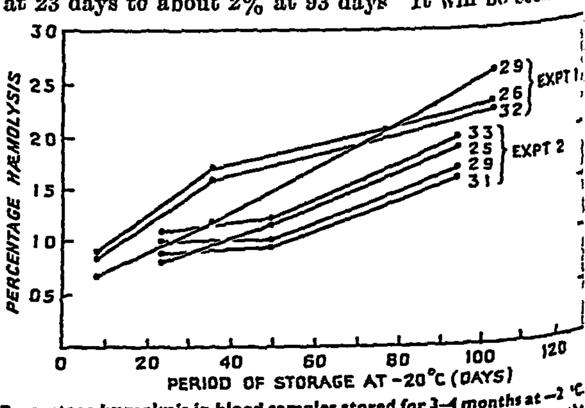
Since storage of large volumes of blood at −79 very costly, it seemed desirable to carry out la experiments at −20°C Lovelock (1953) suggested t glycerol protects red cells from damage at low tem tures by preventing the attainment of high intracel salt concentrations It seemed possible that the us mixture containing 30% glycerol in a hypotonic salt sol might permit satisfactory storage at temperatur high as −20°C Trials of such mixtures were in fact d appointing but, as described below, very sati fa results were obtained when sodium citrate was sub tit for sodium chloride

Glycerol-saline mixtures—Blood mixtures were p pared containing a final concentration of 30% glyc and concentrations of sodium chloride varying fr 0 5 to 1 0% After a week's storage there was l than 5% hæmolysis, but the rate of hæmolysis increa rapidly thereafter, and there was more than hæmolysis in all mixtures stored for more tha month Hæmolysis was least when the sodium chlor concentration was 0 75%

It will be noted that the amount of lysis observed in the experiments is greater than that previously reported b Mollison et al (1952) for blood mixed with glycerol sal This discrepancy is probably due to the fact that in th previous experiments blood drawn into acid citrate-dextro solution was used, and not all the supernatant plasma-citr was removed before adding the glycerol saline In the pre experiments, on the other hand, glycerol saline was added t packed red cells obtained from heparinised blood As we sh now show, the presence of citrate in blood glycerol mixtu stored at low temperatures greatly reduces hæmolysis.

Glycerol citrate mixtures—Blood mixtures were pr pared containing final concentrations of 20%, 25% ar 30% glycerol and concentrations of trisodium citra (dihydric) varying between 2 0% and 3 3% *The be* results were obtained with 30% glycerol and 3% tr sodium citrate, with this mixture there was about 2 *hæmolysis* after 3 months' storage, with *25%* glycer there was about 4 5% hæmolysis, and with 20 glycerol *about 6 5% hæmolysis* Small variations in th concentration of trisodium citrate had little effect, 2 5 and 3 3% being scarcely less effective than 2 9% or 3 1%

Some of these findings are shown in the accompanyin figure In experiment 1, in the mixtures contain between 2 6% and 3 2% trisodium citrate, hæmoly increased from about 1% *at 8 days to 2 5%* at 102 da in experiment 2, hæmolysis increased from about 1% at 23 days to about 2% at 93 days It will be seen tha



Percentage hæmolysis in blood samples stored for 3–4 months at −2 °C In all mixtures the final concentration of glycerol was 30%, the concentration of trisodium citrate is shown against each curve Blood from two donors was used (experiments 1 and 2)

Neurological complications of spontaneous hypoglycæmia.—This theme is too complex for detailed treatment here and I have limited myself to a few clinical observations. It has long been known that hypoglycæmia may be associated with neurological disorders which may persist long after the blood-sugar level has been restored to normal or to hyperglycæmic levels, and which may be irreversible. Their occurrence with insulin overdosage in diabetes mellitus, insulin shock therapy, and pancreatic hyperinsulinism is discussed by Baker (1939) and Fineberg and Altschul (1952). The records of cases 1 and 2 show that similar neurological complications may occur with the coma of pituitary insufficiency, and it is considered that the effects in these cases were due to spontaneous hypoglycæmia. While they lay in coma, both patients had tight jaws and abdominal muscles, intense spasticity of the limbs, tonic spasms, and extensor plantar reflexes; in case 1 the limbs were held in adduction and extension, in case 2 in adduction and flexion. Neither patient responded when the blood-sugar level was restored: case 1 remained in coma and died; case 2 remained unconscious for two days, despite continued treatment, and her complete recovery was preceded by several weeks' madness and signs of organic nervous disorder. The early diagnosis and treatment of spontaneous hypoglycæmia is of vital importance, and three points require emphasis:

(1) Both patients had been subject to recurring mental derangements for several months before unconsciousness, and case 2 was actually in hospital for some time, and had an insulin-tolerance test, before her peculiar mental state was connected with spontaneous hypoglycæmia.

(2) Coma was precipitated in case 2 by a urinary infection, a condition easily overlooked in a confused patient.

(3) In each case the psychic changes and the coma with its neurological accompaniments might have been ascribed to other causes—in case 1 to the intracranial extension of a large pituitary tumour, and in case 2, a woman of 64, to cerebral arteriosclerosis and cerebral thrombosis.

SUMMARY

Clinical findings in 7 women with pituitary insufficiency are presented: 1 was a pituitary dwarf with a craniopharyngioma, and 4 had Sheehan's syndrome. The nature of the lesion was uncertain in 2 patients, of whom one had postpartum and the other postmenopausal onset.

The clinical picture was not uniform, and there were minor disagreements with previous descriptions; the sparing of some pituitary functions and the effects of the syndrome on patients of different constitution are illustrated. Facial resemblance was striking in 4 cases.

Mental changes, coma, and neurological effects in 2 cases were thought to be due to spontaneous hypoglycæmia, and pitfalls in the diagnosis of this condition are discussed.

I wish to thank Dr. Ian Gordon for suggesting this study on his patients, and for his constant advice and encouragement throughout; Dr. A. Lyall for his generous personal help and for all the investigations done by his laboratory staff; Dr. W. Bowman and Dr. W. H. R. Auld for their personal conduct of special tests; Prof. J. S. Young and Dr. A. Wynn Williams for permission to publish the necropsy summary; Dr. C. D. Needham and Mr. W. Martin Nichols for valuable criticism; Mr. R. G. M. Drummond for the clinical photograph; and, not least, the nurses and many resident medical officers for much assistance.

MYLERAN IN CHRONIC MYELOID LEUKÆMIA

CHEMICAL CONSTITUTION AND BIOLOGICAL ACTION

A. HADDOW
M.D., D.Sc., Ph.D. Edin.

G. M. TIMMIS
M.Sc. Manc., F.R.I.C.

From the Chester Beatty Research Institute, Royal Cancer Hospital, London

In an endeavour to enhance the therapeutic efficacy of the nitrogen mustards, in which R = either CH_3 or CH_2CH_2Cl (fig. 1), Haddow et al. (1948) investigated a series of aromatic analogues, of which one member (fig. 2) was subjected to clinical trial and found to have limited usefulness when administered orally in cases of Hodgkin's disease, chronic lymphatic leukæmia, and polycythæmia vera. As an outcome of this work, a series of sulphonic-acid and other esters were synthesised by one of us (G. M. T.), on the assumption that the biological action of compounds of these types might resemble that of the nitrogen mustards because of a common ability to alkylate—i.e., to become linked to some body constituent (X) via the ethane group to form the structure indicated by fig. 3.

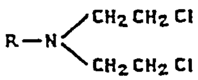

Fig. 1

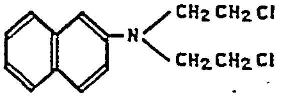

Fig. 2

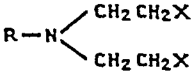

Fig. 3

Of the various types examined, only the sulphonic-acid esters proved active in inhibiting the growth of various tumours in animals, and of these the compound whose formula is given in fig. 4 was characterised by a striking activity combined with a relatively less toxic effect on the bone-marrow than that of the nitrogen mustards (Haddow and Timmis 1951).

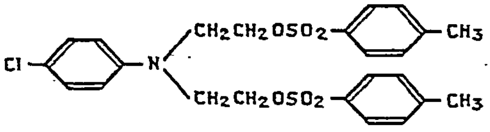

Fig. 4

This result encouraged a further search in the field of the sulphonic-acid esters, and the series of compounds represented by $CH_3SO_2O(CH_2)_nOSO_2CH_3$, in which n may be from 2 to 10, was selected (Timmis 1950) because the relation between chemical constitution and biological action—e.g., inhibition of tumour growth and of hæmopoiesis—could probably best be studied by using the simplest chemical structure possible. Since this structure consists only of the functional groups ($-OSO_2CH_3$) and a chain of CH_2 groups capable of modification by regular gradations, it was hoped that the influence of different numbers of CH_2 groups might here be better assessed than in cases where the structure is complicated, as in fig. 2, by other moieties which might add to the pharmacological complexities.

Various degrees of inhibition of tumour growth (table I) and of blood-cell formation (table II) were observed in the members of this series, and one member in particular, 'GT 41' or 'Myleran' (1 : 4-dimethanesulphonyloxybutane, $CH_3SO_2OCH_2CH_2CH_2CH_2OSO_2CH_3$), showed an intense inhibitory effect on the growth of the has already been shown that storage of red cells mixed with glycerol (final concentration 15%) and saline solution (0 9%) at −15°C† for 3 months has no effect upon the survival-time of the recovered cells (Mollison et al 1952) Experiments are in progress to discover whether cells stored in glycerol (30%) and citrate (3%) also survive normally after transfusion Provided that they do, the only remaining obstacle to the long storage of red cells will be the development of a convenient sterile process for the removal of glycerol

SUMMARY

Red cells mixed with a glycerol citrate solution to provide a final concentration of 30% glycerol and 3% trisodium citrate undergo only very slow hæmolysis when stored at −20°C After 3 months' storage, 98% of the cells remain unhæmolysed, and it seems probable that about 90% of the cells will still be intact at the end of a year Although this method of storage seems certain to be useful in laboratory work, its value in blood transfusion has yet to be proved

REMOVAL OF GLYCEROL FROM PREVIOUSLY FROZEN RED CELLS

A MODIFIED METHOD

H CHAPLIN, JUN ‡ N VEALL
M D Columbia B Sc Lond, A Inst P

From the Medical Research Council Blood Transfusion Research Unit, and the Radiotherapeutic Research Unit, Postgraduate Medical School of London

Sloviter (1951) reported a method for the removal of 15% glycerol from red blood-cells, utilising dialysis through a semipermeable membrane against successively weaker concentrations of glycerol in saline solution This technique was applicable to 500 ml volumes of blood, but was extremely cumbersome and took 48 hours to complete Moreover, elaborate precautions were needed to ensure sterility Lovelock (1952) subsequently described a technique for the more rapid removal of 15% glycerol from red cells by exposing them to strongly hypertonic citrate solution The addition of citrate increases the osmotic pressure outside the red cells and causes water and glycerol to leave the cells, the mixture is then centrifuged, the citrate glycerol supernatant removed, and the cells resuspended in ten volumes of isotonic saline

It has been possible to adapt the citrate method to the higher concentrations of glycerol which are now being used for storage of blood in the frozen state (Chaplin and Mollison 1953) However, in order to process 500 ml of blood, it was necessary to centrifuge it five or six times, and the whole process took 5–6 hours Moreover, when the red cells from an entire bottle of blood are processed in this manner in a standard blood bottle, there is marked "sludging" of the shrunken cells during centrifuging Vigorous agitation is required to resuspend the "sludged" cells in saline solution, and this may be accompanied by considerable additional hæmolysis

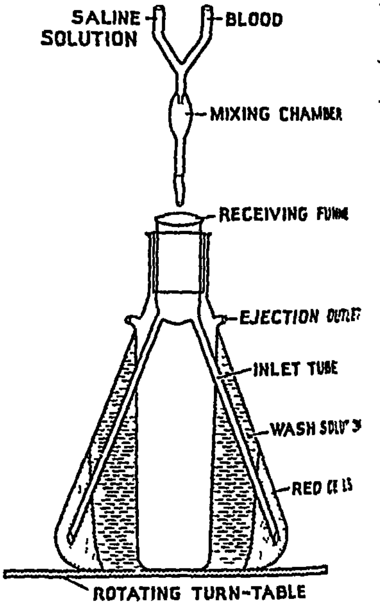
In order to shorten the time required for processing a complete bottle of blood, and to eliminate the hæmolysis associated with "sludging" of the shrunken cells, two main problems had to be overcome

(1) Separation of the cells from their suspending had to be accomplished with the least possible ce force, thereby diminishing the tendency to "sludg

(2) Large volumes of wash solution (up to 5 litre be used, but repeated centrifuging had to be avoided

THE "LONG TRAVERSE CENTRIFUGE" METHO

Buckley et al (1950) described the "long tr centrifuge" method for the continuous washing of cells to free them from their plasma The principle of this method is that the vessel in which the red cells are washed is rotating at a speed great enough to keep the cells at the periphery of the vessel the wash solution is introduced into the peripheral red-cell mass and creates sufficient turbulence to achieve efficient washing The wash solution, being of lower specific gravity than the cells, collects at the centre of the vessel and may be drawn off continuou



Apparatus for the continuous washing of red c

The advantages of applying the "long trav centrifuge" principle to the citrate method for glyc removal are

(1) It is possible to wash the cells while exposing them a centrifugal force of as little as 100 g (compared with 15 2000 g in the standard centrifuge)

(2) It is practicable to use large volumes of wash solut

(3) The suspending medium is removed by continu *dilution and displacement* by isotonic saline solution, t minimising osmotic shock to the shrunken cells

THE NEW APPARATUS AND ITS USE

An apparatus has been designed on this principle f use in the citrate method for glycerol removal As th apparatus is still in a preliminary form, its constructi and use will be described only in general terms Th washing unit consists of an upright conical flask, wi ejection outlets near the neck (see figure) A receiv funnel is fixed in the neck of the flask and from its b several inlet tubes run downwards and outwards to th bottom of the flask The flask is partially filled wi wash solution, and together with its receiving funnel, is rotated as a single unit on a turntable The wa solution takes up a position against the lateral walls the flask, the upper margin being determined by th position of the ejection outlets

To a blood mixture containing 30% glycerol, th necessary quantity of hypertonic citrate solution added This mixture is then allowed to drip into a sm chamber where it mixes with an equal volume of 0 8 saline solution From the base of the mixing chamb the blood flows into the rotating flask After all the blo has entered the flask, washing with 0 85% saline soluti continues until all the glycerol and citrate have be removed Wash solution is continuously ejected fro the outlets at the neck of the flask, and is collected in surrounding glass jacket equipped with suction

This apparatus has been used for fresh red cells i 30% glycerol, and it has been possible to recover 95%

---

† Although it was previously reported that the storage temperature was −15°C the refrigerator used in the experiments referred to is now known to maintain a temperature closer to −20 C

‡ Senior assistant surgeon U S Public Health Service (Res)

e cells 13,700 per c.mm. (neutrophils 70%), no immature being seen.

ase 7.—A stevedore, aged 40, was admitted on March 29, ; with a year's history of night sweats and loss of weight a history of increasing breathlessness since November,), which compelled him to stop work. During the summer 950 his teeth were extracted and he bled excessively on n occasion. A blood-count at another hospital on March 8, 1, showed Hb 9·6 g. per 100 ml. and white cells 336,000 c.mm. (170,016 immature myeloid cells).

n examination he looked fit but was febrile, and his spleen s grossly enlarged. On March 30 his Hb was 6·3 g. per ml., and his white cells were 380,000 (neutrophils 146,300, mature myeloid cells 212,800) per c.mm. (myeloblasts %). In counting 200 white cells 9 nucleated erythrocytes re found. Sternal marrow was hypercellular, and 74% of nucleated cells were immature myeloid cells and 5·8% eloblasts.

Treatment and progress.—Myleran 20 mg. daily was given 5 days from March 31 and from April 9, 1951. Maintenance ses of 2–4 mg. were given from May 3 to July 26, 1951. tal 420 mg. in 118 days. The sweats and dyspnœa ceased thin a month, the patient's general condition improved pidly, he gained weight, and his spleen regressed. From ly 3, 1951, when he returned to work, his spleen was palpable until March 4, 1952, when it could be felt on spiration. By Sept. 2, 1952, the symptoms had returned, e spleen was grossly enlarged, the Hb was 7·3 g. per 0 ml., and the white cells numbered 100,000 (immature yeloid cells 48,000) per c.mm. Treatment with myleran mg. daily was begun, and by Oct. 14 the patient was ck at work, with his spleen regressing, Hb 11·4 g. per 0 ml., and white cells 37,000 (immature myeloid cells 10,000) r c.mm.

Sternal bone-marrow was aspirated on May 4 and Aug. 21, 951, and showed much-diminished cellularity, with a striking elative increase in erythropoietic elements and decrease of ore primitive myeloid cells. On April 1, 1952, marrow smears ontained hypercellular fragments, active megakaryocytes ere relatively numerous, and 3·6% of cells were myeloblasts.

PATIENTS PREVIOUSLY TREATED

Five patients (cases 6, 12, 13, 15, and 16) were referred pecially for trial of myleran.

Case 12.—A married woman, aged 61, was admitted on July 10, 1951, with a month's history of pain in the left flank and over the lower ribs and of lassitude. Chronic myeloid leukæmia had been diagnosed in September, 1947, and courses of radiotherapy to the spleen had been given in November, 1947, February, 1949, February, 1950, September, 1950, and January, 1951.

On examination her general condition was good, but she was febrile and her spleen was grossly enlarged and very firm. The edge of her liver was felt in the right lower abdominal quadrant. A capillary-fragility test was negative. On July 11, 1951, her Hb was 8·3 g. per 100 ml., and her white cells numbered 124,800 (neutrophils 32,947, immature myeloid cells 41,293) per c.mm. (myeloblasts 11·8%).

Treatment and progress.—Myleran 100 mg. was given on July 13 and 25 mg. on July 14, 1951. From July 15 to 28, 1951, 6 mg. daily was given and a further dose of 100 mg. on Aug. 14, 1951. Subsequent courses of 100–150 mg. in daily doses of 25 mg. were begun on Sept. 4, Sept. 18, and Oct. 17, 1951. She became afebrile, her spleen regressed considerably and did not enlarge again. The Hb level remained unchanged. On Sept. 3, 1951, multiple raised discrete pink nodules appeared in the skin of the chest, abdomen, and lumbar region; these increased slightly in size and number during treatment. Her condition deteriorated slowly, and she died on Dec. 17, 1951. Although the initial response was brisk, in the later phases of treatment large doses of myleran had little effect on the leucocyte-count, especially on the immature-cell count. On Aug. 1, 1951, a blood-count showed Hb 10·4 g. per 100 ml., and white cells 13,400 (neutrophils 9045, immature myeloid cells 804) per c.mm. (myeloblasts 1%). On Sept. 7, a blood-count showed Hb 8·5 g. per 100 ml. and white cells 20,000 (neutrophils 5400, immature myeloid cells 12,200) per c.mm. (myeloblasts 21%, many of which were dwarf forms).

Case 13.—A married woman, aged 47, was admitted on June 26, 1951, with a history of pain in the left side since April, 1951, and of excessive bruising after trivial injuries for a year. Chronic myeloid leukæmia had been diagnosed in May, and urethane had been given with little effect.

On examination the patient appeared fit, but her spleen reached the umbilicus. A capillary-fragility test was negative. On July 11, 1951, a blood-count showed Hb 11 g. per 100 ml., white cells 168,800 (neutrophils 124,300, immature myeloid forms 33,700) per c.mm. (myeloblasts 2%), reticulocytes less than 0·5%, and platelets 100,000 per c.mm. Sternal marrow was hypercellular, with 44% of immature myeloid cells; the myeloid-nucleated erythrocyte ratio was 22 : 1.

Treatment and progress.—Myleran 100 mg. was given on July 13, 1951, and 25 mg. next day, followed by 4 mg. daily until July 29. Total 185 mg. in 17 days. Further maintenance therapy (4–6 mg. daily) was given from Sept. 4 to Oct. 2, 1951. The spleen regressed until it was impalpable, and the pain was relieved. On July 23, 1951, sternal bone-marrow was less cellular than on July 12, with 22% of immature myeloid cells and a myeloid-nucleated erythrocyte ratio of 11 : 1. On Aug. 8, 1951, the Hb was 13·8 g. per 100 ml. and white cells numbered 5200 per c.mm., no immature forms being seen. The patient remained well although she bruised easily; but on Oct. 15, 1951, epistaxes and gum-bleeding began, and on Oct. 30, 1951, the platelet-count was 10,000 per c.mm. and Hb 8·2 g. per 100 ml. From then on repeated transfusions of fresh blood were given, but hæmorrhage continued and progressive leucopenia supervened. The iliac bone-marrow on Dec. 12, 1951, was hypoplastic and 84% of the nucleated cells were dwarf myeloblasts. She died on Jan. 7, 1952.

The remaining seven patients who had had other treatment were all treated with myleran because radiotherapy was contra-indicated or was considered unlikely to be of value.

Case 1.—A married woman, aged 37, was first seen on Oct. 5, 1948, with 6 months' history of lassitude, 3 months' history of painless abdominal enlargement, and recent dyspnœa on exertion. She looked ill and her spleen was grossly enlarged. A blood-count on Oct. 19, 1948, showed Hb 7·8 g. per 100 ml., white cells 357,800 (neutrophils 149,909, immature myeloid cells 180,689) per c.mm. (myeloblasts 4%, premyelocytes 9%), and platelets 220,000 per c.mm.

Treatment and progress.—2-Naphthyldi-2′-chloroethylamine was given to a total of 7 g. in 35 days, and radiotherapy to the spleen was given with good effect. Further radiotherapy was given in September, 1949, with equally good result. A third course in May and June, 1950, was followed by short-lived improvement, and splenic regression was less than after previous treatment. On Sept. 26, 1950, she complained of weakness and easy fatigue. Her spleen was grossly enlarged. On Oct. 10, 1950, a blood-count showed Hb 10·7 g. per 100 ml. and white cells 86,600 (neutrophils 33,774, immature myeloid cells 42,000) per c.mm.

Myleran 6 mg. daily was given from Sept. 26 to Oct. 9, and 8 mg. daily from Oct. 10 to Oct. 31, 1950. Total 258 mg. in 36 days. The patient's condition rapidly improved, and on Dec. 19, 1950, her spleen had receded 10 cm. medially and upwards, her Hb was 15·1 g. per 100 ml. (more than at any time since the onset of her illness), and her white cells numbered 26,400 (neutrophils 14,256, immature forms 7128) per c.mm. (premyelocytes 2%). She remained well for a time, but by Feb. 27, 1951, her spleen extended 9 cm. to the right of the midline and almost reached the symphysis pubis, her Hb was 12·9 g. per 100 ml., and her white cells numbered 65,800 (neutrophils 28,294, immature myeloid cells 30,597) per c.mm. (myeloblasts 0·5%, premyelocytes 6·0%). Further myleran given in March, 1951, was followed by a remission which lasted only 2 months, splenic regression being only slight. In May, 1951, radiotherapy of the spleen did not arrest enlargement of the spleen, and thereafter repeated blood-transfusions were required. She died on Oct. 6, 1951.

Case 4.—A married woman, aged 62, was admitted on Jan. 31, 1951, with a history of dyspnœa on slight effort, exhaustion, fainting attacks, and heavy sweats since October, 1950, and more recently of pain over the left lower ribs. She had received eleven courses of radiotherapy between January, 1944, and May, 1950.

On examination she was very pale and febrile. Her abdomen was greatly distended, her spleen almost filled the left side, and the edge of her liver was felt 15 cm. below the costal margin. A blood-count on Jan. 31, 1951, showed Hb 4·5 g. per 100 ml., white cells 134,000 (neutrophils 56,950, immature regard to the barbiturates, the evolution of thiopentone enabled the anæsthetist to obtain a depth of unconsciousness or anæsthesia which could not be obtained safely with longer-acting derivatives Similarly in the relaxant group greater flaccidity is obtainable with succinylcholine chloride than with any other agent, because of its evanescent qualities, succinylcholine chloride administered in a drip gives *safe continuous relaxation at any* desired level

The promise of greatly increased flexibility and safety in controlled hypotension induced by arfonad prompts us to report these preliminary trials

We were fortunate enough to obtain 1200 mg of arfonad, which was brought back from the U S A by one of us (I W M) Because this amount was small we have only been able to investigate the five cases here reported Our trial of this agent in a larger series of cases depends on obtaining further supplies of the drug

STREPTOKINASE and streptodornase offer the surgeon a new biological approach to the treatment of infected wounds, for by helping to remove fibrin and pus they enhance healing

Tillett and Garner[29] observed that broth cultures of certain strains of hæmolytic streptococci caused the rapid lysis of fibrin clots of human blood The lytic factor was subsequently shown to consist of two ingredients, one was a fibrin-lysing system present in the euglobin fraction of the serum,[20] and the second a catalyst produced by the streptococcus[1] The activated fibrin-lysing system liquefied fibrin and inhibited conversion of fibrinogen to fibrin A human group-C strain of the β-hæmolytic streptococcus (H46A), which was found to be a potent producer of streptokinase, has since been used in the development of streptokinase and streptodornase[28]

Crude concentrates containing streptokinase were found to liquefy pus Sherry and his co workers[26] observed that the viscosity of purulent material was due to desoxyribonucleoprotein and desoxyribonucleic acid, a less viscid ribonucleoprotein was also present A distinct enzyme, desoxyribonuclease or streptodornase, causing liquefaction of desoxyribonucleoprotein, was also found to be elaborated extracellularly by the same streptococcus[7 26] Other enzymes have been discovered in the concentrates hyaluronidase,[9 10] a proteinase,[3] a ribonuclease,[7] and several nucleotidases and nucleosidases[5 22]

Sherry and Goeller[5 22] showed by paper chromatography and ultraviolet absorption spectra that streptodornase causes depolymerisation of desoxyribonucleoprotein and desoxyribonucleic acid into many fragments with the formation of nucleotides, nucleosides and finally purine and pyrimidine compounds Because number of products of digestion several enzymes seem to be present For its action streptod requires magnesium ion as a catalyst Streptod acts only on extracellular nucleoprotein and do attack living cells[23]

GENERAL PRINCIPLES

When introduced into a collection of thick pus, st dornase changes the coarse sediment to a thin In this process it hydrolyses desoxyribonucleic which clumps and thus inactivates leucocytes T removal of desoxyribonucleic acid causes a local in motile leucocytes and an increase in phagocyt

Streptokinase and streptodornase have been p many uses Because of the dual or perhaps mul *enzyme systems in the concentrates,* these liquefy and pus in diverse places Originally, streptokinase used to dissolve sanguineous coagulums in the ple cavity[21 27 28 30 31] The discovery of the accompan streptodornase[25] has greatly widened the field usefulness[8 24 25 32] Local application of streptok and streptodornase benefits all wounds containing and pus by lysing the substrates of these substan To be effective the enzymes must be kept in sust contact with the substrates, and this sometimes ca for much thought and ingenuity

Slough and foreign bodies must be manually rem from the wound since they are not susceptible to action of these enzymes *The mucoproteins,* incl mucins and mucopolysaccharides, and collagen likewise not hydrolysed[28] The blood supply to involved area must be good, and auxiliary meas to improve the local blood supply may be nece Streptokinase itself does not lyse fibrin, the fibrin lys system must be carried by the blood to the site of lesion Similarly, magnesium ions must be supplied catalysis by streptodornase

Treatment should be continuous, rather than int mittent Since the products of digestion are thought interfere with healing, they should be removed fa promptly

Streptokinase and streptodornase act at a pH 6–8[23] Their local irritative action produces exudation enough serum to act as an effective buffer, and no spe steps to change the pH before treatment are necessar

Tillett[28] feels that parts of the fibrin lysing system m be depleted locally for a short time after an injection streptokinase, particularly in hæmothorax, so th treatment should be given on alternate days to per reaccumulation of serum factor The pleura, howev responds to sanguineous irritation by a serous effu and it seems to us that treatment should be given dail since we believe that the fibrin lysing system is sufficientl replenished after twenty-four hours

The toxic effects from the local application of strep kinase and streptodornase are practically neglig Elevation of temperature, particularly when the enzym are applied to a closed space, is the commonest side effe Tillett[28] reports a very low incidence of allergic reactio but we have not seen any Hæmatological, hepatic, renal toxic reactions have not been observed[28] Pr thrombin-times do not deviate significantly from normal Hæmatomas and areas of ecchymosis do not result fr the local administration of the enzymes[11] Living tis is not affected

The results are usually so good that failures shou be carefully investigated Even though pus liquefi healing may be hindered by other factors

METHODS OF ADMINISTRATION

These compounds, as supplied in the U S A, have potency of about 100,000 units of streptokinase and 25,000 units of streptodornase per ampoule For th treatment of a sterile or infected hæmothorax or emp ous, and the leucopoietic elements showed relatively mature cells and fewer primitive forms. In case 4 rd sample, examined 9 months after the first dose yleran, appeared normal. In case 7 a third sample n 20 weeks after the first dose, when the neutrophil count had fallen to 450 per c.mm., showed that the marrow was still hypocellular; but a fourth sample, taken when the spleen became palpable a year after the original course of treatment, contained some densely cellular fragments. In case 13 a third sample, examined

CHRONIC MYELOID LEUKÆMIA TREATED WITH MYLERAN

	Age (yr.)	Sex	Previous treatment	General condition before myleran therapy	Splenic enlargement before myleran therapy	Splenic regression after myleran therapy	Hb (g. per 100 ml.) before myleran therapy	Hb increase (g. per 100 ml.) in first 12 weeks after myleran therapy	Length of remission following myleran therapy	Remarks
	40	F	Di-2-chloroethyl-2-naphthylamine; radiotherapy	Poor	Gross	Moderate	10·7	4	5 mos.; 2 mos. second course	Response to myleran better than that to previous course of radiotherapy, which had lost former efficacy
	58	F	Radiotherapy urethane; radioactive phosphorus	Poor	Gross	Slight	6·0	2	3 weeks	Myleran was given during acute terminal relapse; transient remissions only
	60	F	Radiotherapy	Poor	Gross	Slight	5·7	4	10 mos.	As in case 1
	62	F	Radiotherapy	Poor	Gross	Marked*	4·5	5	18 mos. no response to second course	Radiotherapy not given because of poor condition; excellent response to myleran
	71	F	None	Fair	Gross	Marked	10·7	4	21 mos.; remission continues	Excessive dosage of myleran; transient hæmorrhagic phase delayed increase in Hb; subsequent response excellent
	44	F	Radiotherapy	Fair	Moderate	Marked*	9·6	3	3 mos.; no response to subsequent treatment	Acute relapse supervened, perhaps precipitated by excessive doses of myleran
7	40	M	None	Fair	Gross	Marked*	6·3	8	18 mos.; responding to second course	Was considered too acute for radiotherapy; excellent response to myleran
8	60	F	Radiotherapy	Poor	Gross	Slight	12·7	Hb decreased	2 weeks	As in case 2
9	60	F	Transfusions only	Poor	None	..	6·4	Transfused	6 weeks	Radiotherapy to long bones not given, because of hæmorrhagic state; acute relapse followed transient response to myleran
10	47	M	Radiotherapy	Poor	Gross	Slight	6·3	4	6 weeks	Rapid relapse after radiotherapy; resistance to large doses of myleran followed initial clinical and hæmatological response
11	50	F	Radiotherapy	Poor	Gross	Marked	6·0	7	14 mos.; in remission 3 mos. after second course	Radiotherapy not given, because of bruising; excellent response to myleran
12	61	F	Radiotherapy	Fair	Gross	Moderate	8·3	0	2 mos.	Resistance to large doses of myleran followed brief remission
13	47	F	Urethane	Fair	Moderate	Marked*	11·0	3	4 mos.	Pancytopenia with myeloblastic marrow followed large doses of myleran
14	52	F	None	Fair	Moderate	Marked*	10·4	5	15 mos.; remission continues	Excellent response to myleran; generalised diffuse transient pigmentation during treatment
15	45	M	Radiotherapy; radioactive phosphorus	Fair (1st)	Moderate	Marked*	8·1	6	6 mos.	Second remission interrupted by severe infective hepatitis
				Fair (2nd course of myleran)	Slight	Marked*	9·3	4	6 mos. second remission	
16	40	F	Radioactive phosphorus	Fair	Moderate	Marked*	9·6	3	13 mos.; remission continues	Excellent response to myleran
17	69	M	None	Poor	Gross	Moderate	9·3	3	5 mos.	Initially good response to myleran not maintained
18	33	M	None	Fair	Gross	Proceeding	6·8	7	5 mos.; remission continues	Remission proceeding satisfactorily
19	47	M	Transfusions only	Poor	Gross	Proceeding	5·4	4	6 weeks; remission continues	Remission proceeding satisfactorily; decrease in Hb arrested by myleran; brisk increase preceded by reticulocyte peak 17·2%

* Spleen became impalpable.

Non-tuberculous Empyema

The response of non-tuberculous empyema to local application of streptokinase and streptodornase has paralleled that of hæmothorax. Treatment is guided by the temperature of the patient, the character of the aspirated fluid, and repeated radiographs of the chest. 12 cases have been treated, with excellent results.

Non-tuberculous bronchopleural fistula associated with other types of infection is not a contra-indication to treatment with the enzymes. 3 patients with such a lesion have been treated by us, with excellent results.

Resolving Pneumonia

Streptokinase and streptodornase may be applied intrabronchially for the treatment of slowly resolving pneumonia.[16] The pus is composed of fibrin, desoxyribonucleoprotein, living and dead leucocytes, and desquamated bronchial epithelium, and thus is susceptible to attack by the enzymes.

Ocular Infection

A severe ocular infection caused by *Pseudomonas aeruginosa* was successfully treated with combined polymyxin B and streptokinase and streptodornase therapy.[2] In addition to systemic administration of the antibiotic, local therapy consisted in irrigation at intervals of two hours alternately with a saline solution of polymyxin B and a saline solution of the enzymes.

Antro-oral Fistula

Streptokinase and streptodornase were used successfully in a left antro-oral fistula which had ensued after extraction of a tooth, and had been present for about five months.[15]

Numerous irrigations of the sinus had been done without effect. *Streptococcus viridans*, diphtheroids, neisseria, and *Hæmophilus hæmolyticus* were isolated from the pus. The enzymes were instilled into the fistula through a short length of 'Polythene' tubing, which had been introduced through the inferior meatus by trocar puncture. Treatment was given once daily for two days and then twice daily for twelve days. The result was excellent, with disappearance of sinus tenderness and headache, thinning and decrease of exudate, and reduction in the size of the fistula. Twelve days after this treatment was discontinued, a plastic closure of the fistula was done. Treatment with the enzymes was given for a further three days, starting on the day after operation. Final healing was complete.

Postoperative Prophylaxis

Streptokinase and streptodornase are valuable in many postoperative situations where the collection of blood and/or pus is feared. In these conditions the enzymes are administered through a catheter with a second catheter to provide air-vent suction, which is maintained by a Stedman pump. The following are illustrative case records.

ILLUSTRATIVE CASE RECORDS

Case A.—A 23 year old Negro had a large abscess in the right lobe of the liver. About 400 ml. of pus was evacuated through a small incision. Two no. 18 French urethral catheters were inserted into the abscess and the wound was packed open with nylon. Air-vent suction was provided by a Stedman pump. *Strep. anaerobius* and *Strep. fæcalis* were isolated from the pus. The patient was given aureomycin by mouth. Streptokinase and streptodornase were injected into the wound once daily from May 5 to 18, 1951. The catheters were clamped for about four hours after injection of the enzymes to permit digestion, and then suction was re-established. By May 13 the cavity held only about 15 ml. There was no hæmorrhage from the wound during the treatment with the enzymes. The wound was almost completely healed on June 5, when the patient left the hospital against advice.

Case B.—A 43 year old white man had chills, and fever up to about 102°-103° F, owing to an abscess in the left psoas area. On Aug. 7, 1951, the abscess was incised and a large amount of pus released. Two urethral catheters were placed into the depths of the wound. An unidentified gram-negative bacillus was isolated from the pus, and later *Bacterium aerogenes* was isolated. Clinically, however, this abscess was considered to be tuberculous. The right, and then the left, [illegible] were removed at later dates and were shown to be tub[illegible] The patient recieved procaine penicillin G in aqueous [illegible] sion, sulphapurazole, streptomycin, and *p*-aminosalic[illegible] at various times after operation. Streptokinase and [illegible] dornase were injected into the wound once daily from [illegible] to 28. The catheters were clamped for a period [illegible] hours to permit digestion, after which the suction was [illegible] lished. The exudate became thinner and decreased [illegible] in amount. The wound became clean, dry, and much [illegible] and by Aug. 18 it held only about 5 ml. The remainder [illegible] wound closed somewhat more slowly, but was heal[illegible] Sept. 17 when the patient was transferred for further [illegible] ment of his tuberculosis. Repeated radiographs of th[illegible] tebral column showed no evidence of disease. The [illegible] remained healed and the patient was discharged on [illegible] 1952.

Case C.—A 57 year old white man with diabetes [illegible] developed a large postoperative ventral hernia after [illegible] gastrectomy for a bleeding duodenal ulcer on June 2[illegible] The defect measured about 15 × 12 cm. When [illegible] orrhaphy was done on Sept. 18, 1951, the abdominal [illegible] had to be extensively mobilised. The lower portion of [illegible] fascial defect was closed without tension; in the [illegible] portion a piece of fascia lata was used as a patch. Hem[illegible] was as complete as possible; but, because such repair [illegible] commonly followed by collections of serosanguineous [illegible] no. 18 French urethral catheter was placed on each [illegible] the wound down to the deep fascia. 20 ml. of blood [illegible] aspirated from the wound in the next twenty-four [illegible] Streptokinase and streptodornase were injected [illegible] wound every six hours from Sept. 19 to 23. The ca[illegible] were clamped for four hours to permit digestion of th[illegible] after which suction was applied for two hours. Altog[illegible] about 650 ml. of serosanguineous fluid was aspirated fr[illegible] wound during the treatment with the enzymes. The w[illegible] healed uneventfully.

Case D.—A 65 year old white man had a combined [illegible] minoperineal resection done for carcinoma of the rectum [illegible] March 20, 1952. One no. 20 French urethral catheter [illegible] inserted on each side of the perineal wound down to the [illegible] of closure of the peritoneum. The perineal wound was cl[illegible] Streptokinase 74,000 units, and streptodornase 8500 un[illegible] 10 ml. of physiological saline, were injected through one of [illegible] catheters every eight hours. Digestion of the clot proce[illegible] for four hours, and then the suction was reapplied for [illegible] hours until the time for the next injection. This regime [illegible] continued from March 21 until April 7, after which the [illegible] were injected only once daily. About 250 ml. of serosangu[illegible] ous fluid was removed from the wound during the first f[illegible] eight hours and about 125 ml. in the next forty-eight h[illegible] On March 27 the colostomy clamp came off and the colost[illegible] stoma retracted to the deep layer of the fascia. This nece[illegible] tated an operation for the elevation of the stoma. Dehisce[illegible] of the abdominal wound occurred on April 4 and a second[illegible] closure was necessary. Despite the poor healing of th[illegible] abdominal wounds, the perineal wound healed rapidly. [illegible] March 31 the perineal cavity held about 30 ml., and [illegible] April 7 only about 15 ml. The catheters were removed [illegible] April 17. The perineal wound healed by first intention. [illegible] catheter tracts were almost healed on April 24 and [illegible] completely healed on May 1. All wounds were healed [illegible] May 10. The patient was discharged from hospital on May 1[illegible]

This instance shows that the enzymes do not advers[illegible] affect healing, and may even help it. The abdomin[illegible] wounds did not heal; but the perineal wound, wh[illegible] was treated with streptokinase and streptodornase healed well.

A similar method of treatment was used in a 25 year-o[illegible] Negro who had multiple gunshot wounds with a rect[illegible] perforation and an extensive retroperitoneal hæmatoma.

Surgical therapy included a colostomy, repair of the re[illegible] laceration, insertion of two urethral catheters well into th[illegible] retroperitoneal area, and placement of a rectal tube pe[illegible] the site of repair in the rectum. Streptokinase and strep[illegible] dornase were given through the catheters. Air-vent suct[illegible] was used to remove the products of digestion. An excell[illegible] result was obtained.

The streptokinase and streptodornase were supplied by th[illegible] Lederle Laboratories Division, American Cyanamid Compan[illegible]

DIFFICULT DELUSIONS

I. Atkin
M.D. Lond.

PHYSICIAN-SUPERINTENDENT, PARK PREWETT HOSPITAL;
PSYCHIATRIST, ROYAL HAMPSHIRE COUNTY HOSPITAL

ONE of the more important criteria on which both doctor and lawyer rely when assessing a person alleged to be of unsound mind is the presence of delusions; and yet there are occasions when a decision as to whether a particular belief is delusional or not may prove difficult. Fortunately it is not solely on the presence of delusions that mental illness is most often decided; we diagnose, for example, a state of mania not merely because a person expresses delusions of grandeur, but because he is also euphoric, overactive, exhibits a flight of ideas. However, there are instances where delusions are almost the only symptoms in evidence—other disturbed features of the mind being at a minimum, as in various paranoid states—and then it becomes important to assess the nature of the supposed delusional statement. If a person says that he is made of glass or is King of Siberia, we need not investigate further; if he alleges that he is suffering from diabetes, we can make the appropriate physical investigations to settle the issue. But if the statement is within the bounds of possibility and cannot be decided by a simple examination—e.g., that the neighbours annoy him or that his wife is drunk and unfaithful—then careful questioning not only of the patient but also of relatives, friends, neighbours, or employers may be necessary. The opinion of the family doctor who knows the home and neighbourhood can be of great assistance in such cases. He may have witnessed a relevant scene or quarrel which will enable a judgment to be made with some confidence.

It might be thought, inasmuch as from the social point of view it is the outer behaviour of the person which matters rather that his inner beliefs, that an assessment of the latter is of no great practical importance, and indeed in many cases this is so. A man who is deluded that the earth is flat, or that he is a reincarnation of Tutankhamen, but who remains well behaved and continues to perform his usual social duties satisfactorily is not a case for treatment by the psychiatrist in practice. There are many eccentric paranoiacs in society whose most abnormal behaviour is no worse than preaching in Hyde Park. They are quite happy and are only seen by the psychiatrist who happens to take a stroll in the park. When, however, behaviour is affected in such manner as to disturb other members of society, an assessment of the alleged delusions becomes important: if the person is deluded, there is a mental illness which requires treatment; but if he is not, the abnormal behaviour may fall in the criminal category.

SOME DIFFICULTIES

A variety of difficulties may present themselves when attempting to decide whether a person's statement is delusional or not. Assessment may become a problem when:

(1) There is some basis of fact.
(2) A deluded psychotic utters a statement which seems far-fetched but could be true.
(3) Pseudologia, malingering, or lying is a probability.
(4) Delusion conforms with reality.
(5) A delusion is reinforced by the environment, which had reacted appropriately to a psychotic's odd appearance or behaviour.
(6) Reality plays into the hands of the delusions.
(7) Conduct is not disturbed and the patient is evasive.

Perhaps the most common instance is where there is some basis of fact, which is exaggerated, elaborated, or misinterpreted. The undue stressing of some items in a topic of conversation is such a common human trait that it can hardly be called pathological, and most of us have exhibited such artistry when recounting our favourite yarns. Misinterpretation is a distortion of a more serious nature. The delusional jealousy of Leontes in *The Winter's Tale* is based on a misinterpretation of Hermione's friendship for Polixenes, and this typifies a situation often seen in psychiatric practice.

Again, not all the statements made by an obviously psychotic patient are delusional; but when a number of beliefs seem to fit into a recognised syndrome there is the danger of classifying them all as delusional, though some may be statements of fact. A hypomaniacal patient claimed to know personally all the distinguished political leaders of Europe and also boasted that he was well versed in about a dozen languages—all of which was recorded as delusional. It turned out that the second claim was true. A coloured patient, suffering from dementia paralytica, was euphoric and expressed a number of grandiose delusions; he claimed that he was a king. Information received revealed that in fact he was king of an African tribe.

The patient may be confabulating with varying degrees of awareness, as in malingering or hysterical pseudologia. Evidence of possible motivation, such as a desire to avoid prison or service in the Forces, will put the psychiatrist on guard. Addicts can lie brazenly in an attempt to obtain the appropriate drug, or when excusing their disturbed conduct.

Case 1.—A married man was admitted on an urgency order, in which the wife recorded that he had threatened her life and that he was an alcoholic. When examined the patient was lucid, polite, and well behaved. He minimised his drinking and alleged that his wife also drank and had aggravated him. It was impossible to get at the truth amidst the many accusations and counter-accusations. The minutes) In the 4 cases the skin became shiny, and a punctate erythema appeared, followed by diffuse petechiæ

DISCUSSION

The use of phenylbutazone in rheumatoid arthritis, as seen from our 34 cases, seems to increase mobility and muscle power, and reduces pain to a significant degree, and the first two effects appear to depend on the relief of pain In 6 patients joint swellings diminished, possibly because joint mobility increased, on the other hand, joint swellings increased in 2 patients, and an effusion into a knee-joint developed during treatment The changes in E S R were inconclusive, and there were no significant changes in white cell counts Thorn's test and 17 ketosteroid estimations, which were carried out in 8 rheumatoid patients having phenylbutazone, showed no changes similar to those known to occur with adrenocorticotropic hormone The analgesic effect, as seen in rheumatoid arthritis and osteo-arthritis, seems to be phenylbutazone's major quality

On these experiences we consider that phenylbutazone has a place in the management of chronic joint disease in which the outstanding feature is pain, for it seems to relieve pain more readily than the usual aspirin and codeine mixtures we have used in the past

Toxic effects appeared in 22 out of the 50 patients, and were often quite severe The careful selection and constant supervision of patients who receive th are therefore very necessary

In the selection of patients, we consider that history of peptic ulceration, or the presence of tension, chronic bronchitis and emphysema, or heart-disease with a past episode of failure are al contra-indications because cardiac failure may salt and water retention

SUMMARY

34 patients with rheumatoid arthritis and 1 osteo-arthritis had courses of oral or intram phenylbutazone (butazolidine)

The clinical effects and toxic manifestations hav discussed

It is thought that phenylbutazone is prim potent analgesic in joint disease, but its indiscr use is not without danger

We would like to thank Dr Francis Bach and Dr Ellman, under whose care these patients were trea their interest in this study Our thanks are also Messrs Geigy, and particularly to Mr N Peter A.R I C, who provided the early supplies of phenylbu

New Inventions

MALTBY'S SUTURE-HOLDER FOR FULL-THICKNESS SKIN GRAFTING

THE instrument described here was designed by Mr John T Maltby, my senior theatre orderly at St James's Hospital, Leeds It is an adaptation of Prof T P Kilner's ligature-holder which is attached to his Shadwell gag used for repair of the palate

In any operation where it is necessary to leave many of the sutures long, the ends are apt to become tangled in an exasperating manner unless secured and held out of the way For instance, when a full-thickness skin graft is sutured in position, it is usual to leave alternate stitches long, so that at the end of the operation they can be tied over sponge rubber to fix this securely over the graft After the stitches have been inserted, it is a great advantage to anchor each suture in a wire spring (fig 1) so that the strings radiate from the wound like the spokes of a wheel from the hub (figs 2 and 3) A strong but malleable wire, curved in an ellipse, acts as a framework for the wire spring, being malleable, it can be adapted to fit the irregular contours of the face The framework is fixed to the operation sheets with towel-clips inserted through loops on each side of the ring When all the stitches have been inserted and the sponge applied, two of the sutures, diagonally opposite to each other, are released from the wire spring and over the sponge

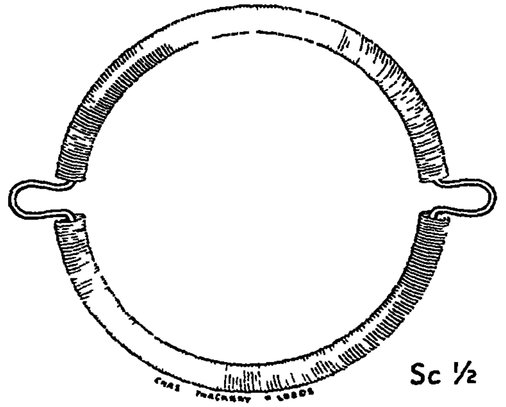

Fig 1—Maltby's suture-holder for full thickness skin grafting

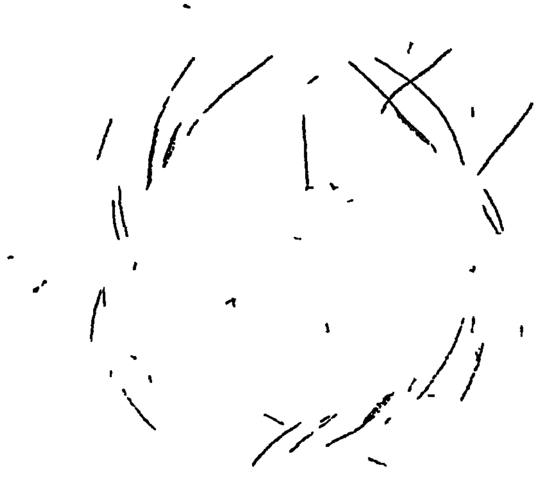

Fig 2—Ligature holder in position The full thickness skin gra been sutured into the defect, some of the sutures have bee long so that they can be tied over the sponge which is used to f graft in position The long ends of the sutures are held o the way in the spring of the suture-holder Towel clips, ins through rings in the suture-holder are fixing it to the ope towel

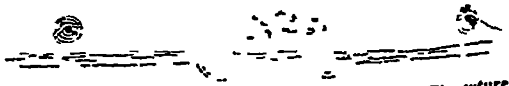

Fig 3—A cross section of full thickness skin graft. The sutures been left long and are held out of the way in the spring ligature car The sponge, over which the ligatures will be tied later, is lying the graft.

This little gadget ensures an orderly procedure obviates the chaos which is so likely to develop if or twenty sutures are left long and to their own dev

ient : That is possible. But there was animosity st me—and I cannot blame them—after I had exposed nproprieties I have mentioned.

this case no useful purpose could have been served ending the psychiatric social worker to investigate. in other cases help may be obtained by a visit to the e of employment or home of the patient.

ise 6.—A woman, single, aged 27, was referred because iad complained that her workmates accused her of stealing of being pregnant. On examination she was found to be tally defective (intelligence quotient 63%) and poor at aining herself. She was the type of person who would nade a butt by others, and her sister felt sure that it was leg-pulling" by the other employees. It was of import- to assess the exact nature of the patient's beliefs, as hizoparanoid reaction was a possibility. The psychiatric al worker was asked to visit the place of employment after lengthy interviews with the manager and several loyees came to the firm conclusion that the patient was ressing delusional ideas.

t will be helpful to question relatives, friends, and ghbours. Indeed, in a difficult case, one cannot seek many sources of information. It must be admitted, vever, that on occasion a multiplicity of informants prove confusing for a variety of reasons, and careful ting out will be required. Sometimes there are family ds (e.g., a sister will support the patient's unjustified gations against his wife). Sometimes there is a *folie nmuniquée* involving the patient and several members his family. The opinions of neighbours are often verted through local gossip or their own specific nplexes. An informant may have personal reasons denying truthful statements made by a patient if h reflect badly on himself. If, for instance, the patient tes (truthfully) that the domineering or cruel attitude a relative has harmed him, such relative is not likely admit this, especially if other relatives have implied t this was a cause of the patient's breakdown. On other hand, confirmation by a relative of a patient's gation is not necessarily foolproof—very often the ative is merely repeating a communicated allegation. is obvious that the greatest tact and diplomacy is quired when questioning informants, and their reaction ist be carefully watched. But with the greatest care ere will be the occasional case where one feels that thing less than living in the home of the patient can cide a certain item; in one such case the family ctor exclaimed, in the face of accusations and counter- cusations between husband and wife, "Where the truth s, Heaven knows!" The following case illustrates w the reactions of an informant help in assessing the lue of the patient's beliefs.

Case 7.—A married woman who suffered from a depressive iction blamed many years of marital disharmony for this, d related details of her husband's misbehaviour. When questioned him, he became very irritable, and refused to swer, merely saying, "She should not have discussed r intimate married life. I will certainly not do so." I inted out that without his coöperation I could not decide iether the patient's allegations were truth, lies, or delusions, it he still refused to discuss the problem. I naturally me to the conclusion that the patient's statements had a od basis of truth.

SUMMARY

It is sometimes difficult to evaluate the possible elusional nature of a patient's statements if one con- ders the bare content, which may not obviously disagree ith a reality situation. Criteria which can help are the anner of presentation by the patient and informants, ieir reactions to questioning, and the evidence afforded y the family doctor, social workers, and psychiatric ocial worker.

I am indebted to Mrs. A. Smith, the psychiatric social orker, to Mrs. K. Wade, the social worker, and to many eneral practitioners for their help in unravelling a mélange f truth, exaggeration, distortion, prevarication, and delusion i difficult cases.

IMPROVED STORAGE OF RED CELLS AT -20°C

H. CHAPLIN, JUN.*
M.D. Columbia

P. L. MOLLISON
M.D. Camb., M.R.C.P.

From the Medical Research Council Blood Transfusion Research Unit, Postgraduate Medical School of London

FOLLOWING the observation of Polge, Smith, and Parkes (1949) that glycerol would protect spermatozoa against the effects of low temperatures, Smith (1950) showed that red cells could be similarly protected. Subsequent work on the storage of red cells in the frozen state was reviewed by Mollison, Sloviter, and Chaplin (1952), who described the results of experiments in which red cells were stored at −15°C or −79°C for long periods and then used for transfusion. In these experiments a concentrated suspension of red cells was mixed with an equal volume of a glycerol-saline solution before freezing. It was found that red cells recovered after storage had virtually unimpaired viability. However, the proportion of cells lost during freezing, storage, thawing, and dialysis was considerable, only about 50% of the red cells being recovered after storage for 6 months at −79°C or after 1 month at −15°C. It was emphasised that before storage of red cells in the frozen state could be of practical value in transfusion work, the proportion of red cells recovered after storage would have to be increased and a simple method of removing glycerol devised.

The present paper demonstrates that very low rates of hæmolysis can be achieved by a simple modification of the original method, and that with this modification satisfactory storage is possible at −20°C. Thus any laboratory can now store red cells for at least a year in an ordinary deep-freeze cabinet. This should be particularly valuable to blood-grouping laboratories since storage in the frozen state does not appear to affect the serological reactions of red cells (unpublished observations).

To establish the value of the new method in transfusion practice it must be shown that red cells stored in this way survive normally after transfusion. Experiments are in progress to discover whether this is so.

METHODS

Blood-glycerol Mixtures

One volume of glycerol-saline (or glycerol-citrate) solution was added to one volume of packed red cells, obtained either from fresh heparinised blood or from blood mixed with acid citrate-dextrose solution and previously stored at 4°C for 1–3 days. Hæmolysis could be minimised by first warming the glycerol and red cells at least to room-temperature, and then adding the glycerol to the red cells relatively slowly while agitating the mixture.

The concentration of sodium chloride or of sodium citrate in the various mixtures mentioned below is the concentration (weight/volume) in the glycerol-saline or glycerol-citrate solution which was added to the packed red cells. However, glycerol concentrations have been calculated on the assumption that glycerol diffuses freely into a volume equivalent to 60% of the red-cell mass. The specific gravity of the glycerol was taken as 1·24, since the preparation used was known to contain only 97% glycerol. Thus if one volume of undiluted glycerol plus one volume of 6% trisodium citrate solution were added to two volumes of packed red cells, the citrate concentration would be given as 3% and the glycerol concentration (*w/v*) as:

$$\frac{\text{Weight of glycerol}}{\text{Volume of glycerol-citrate mixture} \div 60\,\%\text{ of volume of red cells}} = \frac{1{\cdot}24}{2 \div \frac{(60\times 2)}{100}} \times 100 = 40\,\%.$$

---

[*] Senior assistant surgeon, U.S. Public Health Service (Res.).

and carping in criticism "Dr Singer's comments are querulous and niggling" and are described "as talk of the kind one expects to hear in club corners" Mr Ivins bases his essay on a study of the original woodcuts, and of books and articles dealing with Vesalius He concludes that the illustrations were drawn by John Stephen of Calcar without help from Vesalius, who merely wrote a commentary on them. Stephen therefore is the hero of *De Fabrica*

This essay will arouse vigorous discussion among historians, who will find the book of great interest even if parts are infuriating

Visceral Circulation

A Ciba Foundation Symposium Editor G E W WOLSTENHOLME, O B E, M B, assisted by M. P CAMERON, M A, and J S FREEMAN, M B London · J & A Churchill. 1952 Pp 278 30*s*

IN the recent symposium on the visceral circulation, held in London by the Ciba Foundation, 49 guests took part, comprising anatomists, physiologists, biologists, biophysicists, biochemists, pharmacologists, and clinicians in medicine, surgery, and anæsthetics This admirable book of the proceedings contains summaries of papers presented by each of the 25 speakers, and of the discussions which followed There are contributions on visceral vascular structure, vascular patterns in the alimentary canal, vascular architecture of the kidney, the laws of physics and the flow in blood-vessels, sympathin production and excretion, visceral blood-vessels as pain perceptors, afferent paths of cardiovascular reflexes, aortic and coronary flow, determinants in hepatic hæmodynamics, vasoconstriction and vasodilatation in the normal and failing circulation, physiological changes during fainting, and many other subjects of topical and permanent interest

The Knee and Related Structures

Injuries—Deformities—Diseases—Disabilities PHILIP LEWIN, M D, F A C S, professor of bone and joint surgery, Northwestern University Medical School London Henry Kimpton 1952 Pp 914 120*s*

IT is difficult to see to just which section of British medicine this massive book will prove attractive As a monument to the industry of the author it is comparable to his previous volume on the foot, any subject with any conceivable connection with the knee has been included It is too vast a book for the student, while insufficiently eclectic and perhaps too "popular" in style to be likely to appeal to orthopædic surgeons in this country But it has at least collected an immense amount of material under one cover One cannot but admire the hard work that has gone into this volume, but the result remains very indigestible

Lumbar Disc Lesions

Pathogenesis and Treatment of Low Back Pain and Sciatica J R ARMSTRONG, M D, M CH, F R C S, orthopædic surgeon to the Metropolitan, Lambeth, and Manor House Hospitals Edinburgh E & S Livingstone 1952 Pp 228 42*s*

Mr Armstrong's extensive experience of lumbar disc surgery qualifies him to write a more engaging clinical account of the subject than he offers us here The style is somewhat dry and didactic, and, though diagrams and arguments about lumbar mechanics abound, case-histories and radiographs would have been more refreshing It is not made clear that senescence and degeneration of the discs is a universal and indeed normal process, nuclear pathology is emphasised at the expense of annulus lesions, and nothing is said on the newer developments in discography and the electron-microscope study of ground structure In the clinical section Mr Armstrong underestimates, we think, the value of the plaster-jacket, which, efficiently applied and renewed as necessary, makes bed rest or other fixation unnecessary for the great majority of acute cases Manipulation, epidural analgesia, and the local anæsthesia of sites of referred tenderness are all decried, on largely theoretical grounds, though experience shows that, used judiciously, they may greatly ease those patients, often decrepit or elderly, who are unfit for plaster or laminectomy and who would be rotted by bed rest Lest these criticisms seem ungrateful, we should add the important fact that the book succeeds in presenting every fact relevant to diagnosis, differential diagnosis, and treatment of lumbar disc lesions, including the indications for operation and the technique of laminectomy and spinal fusion.

Intracranial Aneurysms

WALLACE B HAMBY, M D, *professor of neurosurgery*, University of Buffalo School of Medicine and Dentistry, Buffalo General Hospital Springfield, Ill: Charles C Thomas Oxford Blackwell Scientific Publications 1952 Pp 564 £5 2*s* 6*d*

INTEREST in intracranial aneurysms has much increased during the past ten years with the development of percutaneous angiography and more radical surgical methods of treatment A monograph on the subject was needed, and this book, besides giving a clear account of the clinical syndromes caused by intracranial aneurysms in various situations and the possible methods of treatment, also describes arteriovenous malformations The style is informative rather than inspiring, and the text is broken by a series of case-histories The clinical and pathological illustrations are good, but the definition of the angiograms varies greatly and in some it is difficult to see the vessels clearly There is a useful bibliography

Human Milk

Yield, Proximate Principles and Inorganic Constituents S D MORRISON, B SC, Institute of Physiology, Glasgow University Farnham Royal Commonwealth Agricultural Bureaux 1952 Pp 91 10*s* 6*d*

IN this book is collected much of the information in the literature on the yield and chemical composition of human milk Besides the three major constituents and related compounds (nitrogenous—mainly protein materials, lipids, and carbohydrates), it deals only with minerals No consideration was given to the vitamin content because this aspect of the subject has recently been comprehensively covered by Kon and Mawson (Medical Research Council Special Report Series no 2 1950) Mr Morrison not only brings together many interesting data from papers published in a wide variety of journals, some of them not readily available, but presents them critically, sometimes recalculating statistics so as to make comparison easier He is often on less sure ground when he theorises, as he does here and there on the biochemistry of milk formation

---

Forensic Medicine (2nd ed London Edward Arnold 1952 Pp 344 21*s*)—Dr Keith Simpson's textbook, as attractive and lucid as his lectures, is now brought into line with the last year or two's forensic progress It is encouraging to see that the chapter on war gases has given way to one on poisonous plants and fungi The new chapter usefully sums up their lethal properties, and it will be all the more welcome now that the trifling monograph on this subject by a Baker Street toxicologist is out of print

Muscle Relaxation as an Aid to Psychotherapy (London Actinic Press 1952 Pp 65 5*s* 6*d*)—This little book is written primarily for physiotherapists, to enable them to give effective relaxation exercises to certain types of psychiatric patients The author, Dr Gerald Garmany of the Westminster Hospital, points out that the use of relaxation in psychiatry is limited, and that it cannot by itself effect cure in cases of muscular tension due primarily to emotional disturbances By abolishing tension and in teaching the anxious patient how to relax properly, the techniques described may, however, bring about a better all round adjustment to the stresses of life The ways in which emotional disturbance can affect bodily functions and muscle tension are clearly described, the James Lange theory and the work of Jacobson are discussed, and the part that bodily feelings play in emotional states is not overstressed The need for coöperation and a working knowledge of the technique used by the other partner in the joint enterprise of psychotherapist and physiotherapist is constantly borne in mind There is a chapter on *indications* for the treatment and its difficulties, and another on the types of concurrent psychotherapy The book is very well written, concise without being dry, and authoritative without being dogmatic rates of hæmolysis remained approximately constant these periods. If hæmolysis continued at the rates n in the figure there would be only 7% lysis at the of a year.

n an experiment in which disodium citrate (mono- ric) was substituted for trisodium citrate, mixtures aining 2·4% and 2·6% showed just over 1% hæmo- s at 23 days and slightly less than 2% hæmolysis at days. These results are not significantly different n those obtained with trisodium citrate. It was noted, ever, that when disodium citrate mixtures were added red cells, considerable lysis resulted unless some itional plasma was left with the packed red cells.

n another experiment red cells from blood mixed with d citrate-dextrose solution were used instead of cells m heparinised blood: the rates of hæmolysis were entially the same.

n a further experiment the effect of storing cells shed free from plasma was investigated. 12 ml. of ked red cells were washed three times with 15 ml. of ine solution, and then mixed with 12 ml. of a mixture ntaining 2·9% trisodium citrate and sufficient glycerol give a final concentration of 30%. As a control, 12 ml. unwashed packed red cells were mixed with the same cerol-citrate solution. After 93 days' storage the xture containing the washed cells showed 1·4% molysis, whereas the control showed 2·4%. Little phasis can be placed on such small differences, but it at least be concluded that washed cells do not molyse any more rapidly than unwashed cells under se conditions.

fect of Repeated Freezing and Thawing at −20°C and 79°C

Blood mixtures containing 30% glycerol and 3% sodium citrate were divided into four bottles, two ing stored at −20°C and two at −79°C. One bottle each pair was thawed weekly for sampling, and the cond was stored without interruption until the end of e experiment. In the bottle which was repeatedly awed and refrozen to −79°C, hæmolysis increased rogressively and amounted to 28% after 6 weeks, hereas the bottle kept continuously frozen showed only % hæmolysis at that time. On the other hand, of the air stored at −20°C, the repeatedly thawed bottle owed less than 4% hæmolysis after 6 weeks, compared ith 2% hæmolysis in the control. Thus, repeated freezing nd thawing causes very little hæmolysis when the orage temperature is −20°C, but considerable hæmo- sis when the temperature is −79°C.

ractical Procedures

The following method is recommended for the storage f small blood samples (up to 5 ml. of packed cells). repare packed cells by centrifuging heparinised or itrated blood for 30 minutes at 3000 revolutions per ninute, and removing almost all the supernatant plasma. Now add to the volume of packed cells an equal volume of glycerol-citrate mixture, prepared by mixing 4 volumes of glycerol with 6 volumes of 5% trisodium citrate solution. Add the glycerol-citrate mixture in stages, agitating the ube continuously. Then place the tube in an ordinary deep-reeze cabinet at about −20°C. As noted above, the same ube of blood can be repeatedly frozen to −20°C and hawed without much increase in hæmolysis. However, t is often convenient to divide the mixture between everal small tubes before freezing, so that a small quantity can be thawed out at a time.

For the recovery of the red cells, prepare three solutions containing respectively 16%, 8%, and 4% of glycerol (w/v) in 3% trisodium citrate. Thaw the tube of blood by placing it in tepid water; then transfer the blood to a 1 oz. bottle ("universal container") and fill it to the top with the 16% glycerol solution. Mix well and centrifuge at 3000 r.p.m. for 5 minutes. Replace the supernatant with the 8% glycerol solution, then with the 4% solution, and finally with 1% saline solution. With this method red cells can be recovered in 1 hour with very little lysis.

When larger amounts of blood are to be stored for transfusion, the procedure is essentially the same. The red cells are packed by centrifuging the whole bottle. The bottle is then provided with an air outlet by passing a short needle through the rubber diaphragm of the bottle. The supernatant plasma is now removed through a long sterile needle plunged through the rubber diaphragm. Sterile glycerol-citrate mixture is then run in through a short length of rubber tubing with a wide-bore needle at each end. It is convenient to autoclave about 220 ml. of glycerol-citrate solution in an ordinary blood bottle, and to run this by gravity into the bottle containing the red cells. The bottle containing the glycerol-citrate solution must be provided with a long sterile needle as an air-inlet. The bottle containing the red cells is rotated while the glycerol-citrate mixture is run in, the whole procedure taking about 10 minutes. The bottle can then be frozen. (It is recommended that, before freezing, a sample of the mixture should be taken through the rubber diaphragm using a sterile needle and syringe; this sample may be cultured at room-temperature and at 37°C, adding 1 ml. of the blood-glycerol mixture to 50 ml. of nutrient broth.)

To prepare the red cells for transfusion, a method based on that described by Lovelock (1952) has been tried. The modified method consists in replacing the supernatant with 12–15% citrate solution and washing the red cells four or five times with saline solution to obtain a clear supernatant. With the ordinary large bottle centrifuge the process takes 5–6 hours. Moreover after the addition of hypertonic citrate there is gross "sludging" of the red cells and this leads to considerable additional hæmolysis. The method described above for small samples should give better results, but it also is too time-consuming to be convenient for large volumes of blood. These difficulties should be overcome by the further development of the continuous washing device described by Chaplin and Veall (1953).

DISCUSSION

It is of considerable interest that red cells can be frozen to −79°C and stored at that temperature with much less lysis if the final glycerol concentration is raised from 15 to 30%. However, the interest of this observation has been eclipsed by the discovery that if a citrate-glycerol rather than a saline-glycerol solution is used, red cells can be satisfactorily stored at −20°C. Disodium citrate appears to be as effective as trisodium citrate, but since most of the experiments have been made with the trisodium salt and since this salt is more readily available, it has been specified in the procedures recommended here. Although the reason for the superiority of sodium citrate over sodium chloride is not fully understood, it is presumably related to the fact that citrate does not penetrate the red cells.

The fact that when red cells are mixed with an appropriate glycerol-citrate solution and stored at −20°C a high proportion (probably more than 90%) can be recovered after a year is of considerable importance. It means that any laboratory equipped with an ordinary deep-freeze cabinet can keep samples of red cells for long periods at a negligible cost. This should be of particular value to blood-grouping laboratories.

The high cost of maintaining bottles of blood at −79°C can be illustrated by an example: in this laboratory an insulated box holding about thirty bottles of blood required more than £120 worth of carbon dioxide in a year, a cost of £4 per bottle per year. This is probably 80 times the cost of storing a bottle of blood at −20°C for a year.

The time has come to consider whether this method of storage would be useful to transfusion-services. It

Since first impressions are often lasting, the council are anxious that our hospitals should display themselves favourably from the start The patient (who is often low-spirited when he arrives at hospital) needs a friendly greeting, and the council attach particular importance to the personality of the person receiving him They suggest that a lay receptionist *of the right type is often suitable*, but it does not much matter who does the work provided she is kind, smiling, and sensible Then, the patient should be shown the way to the ward or department he is seeking, or should find the route well posted with signs, and he (and his visitors) should be allowed the use of lifts for surely the patient is more important than his dinner or his washing, and at least as important as the senior consultant, of whose very existence he is, after all, the cause Incidentally it is not the consultant, as a rule, who wishes to enjoy amenities denied to the sick he is merely a victim of the hospital practice (deriving from a very different age) of deifying the doctor according to a set of unwritten laws In some hospitals one of these laws, the council point out, decrees that neither bite nor sup shall pass a patient's lips while a doctor is in the ward, and many a meal is thus delayed while patients chafe and rumble The council rightly believe that few members of the medical staff would wish to see the rule maintained, and suggest that it should be abolished In hospital, as on sea-voyages, meals acquire a significance quite out of proportion to their intrinsic merit they are the only counterpoint to a dull tune, and should keep strict time

The council note how little thought is nowadays given to noise in hospitals (though it was, of course, a matter to which Miss NIGHTINGALE gave a good deal) They suggest that every hospital should analyse causes of noise, with the help of patients and staff, and find means of removing them One modern source of noise is the loudspeaker, and there is no excuse for it when earphones and pillow-phones can so easily replace it Trolley wheels are another, but there are silent wheels on the market Short visiting periods should be allowed daily whenever possible, with one or two longer periods for the convenience of those who come from a distance When the patient leaves hospital the family doctor takes over, and he ought to be properly and quickly informed of the stage his patient's illness has now reached Too often he has to wait weeks for information which, in the patient's interests, he ought to have at once Would such slipshod methods be tolerated if the patient were being transferred from one department to another within the hospital?

The many other recommendations made in this memorandum for the patient's well-being or comfort cannot be enumerated here, but it is worth noting that the council have not asked for a large outlay of anything much beyond kindness, forbearance, and good manners "We see no reason," they say, "why financial stringency should prevent the carrying out of the greater part of our recommendations" Where funds are needed voluntary societies will often be willing to help, and every hospital should think of forming its own group of "friends" How much such friends can accomplish we have only recently told [2]

Blood Hazards in Industry

MENTION of industrial hazards usually conjures up pictures of whirling unguarded belts, crushed hands or diseases like "hatters' shakes" and cancer of the bladder in aniline workers The modern industrial hazard is more insidious but just as dangerous, and *many of these hazards affect the blood* In the second Ernestine Henry lecture to the Royal College of Physicians, Prof R E LANE [1] reviewed these blood hazards and criticised methods of assessing and preventing them

Industrial poisons can affect either circulating blood or blood formation in the bone-marrow; in the peripheral blood they may act on the hæmoglobin by changing it to forms like methæmoglobin which are valueless for the transport of oxygen, or they may actually hæmolyse red cells Thus arsine gives rise to hæmolysis, aniline to methæmoglobin and also some hæmolysis, and benzene and ionising radiations to failure of hæmopoiesis Of the hæmoglobin changes, the best known is the formation of carboxyhæmoglobin by exposure to carbon monoxide Methæmoglobinæmia, often accompanied by some sulphæmoglobin and methæmalbumin in the blood, gives rise to cyanosis, and in industry it is usually caused by organic nitro or amino compounds Professor LANE points out that many such substances are used in industry while new ones are constantly being introduced, they are especially dangerous because they can be absorbed through the skin and through the respiratory tract Arsine, the worst hæmolytic poison is a not uncommon industrial hazard, LOCKET et al have collected reports of such poisoning from several industries, including electroplating and the smelting, refining, and galvanising of metals The most familiar industrial hæmolytic poison is lead, which is used extensively Work by RIMINGTON [3] and by Professor LANE and his co-workers [4] has shown that lead also interferes considerably with hæmopoiesis by impairing hæmoglobin formation Aplastic anæmia became a prominent industrial hazard in the first world war since it is liable to follow exposure to trinitrotoluene Benzol, which is also known to cause aplastic anæmia, is widely used as a solvent, and Professor LANE mentions the production of rubber cement and of quick-drying inks, and the leather industry, as providing conditions in which exposure cannot be easily controlled With benzol it is the continual daily exposure that is dangerous, and the safe limit of 35 parts per million proposed by the International Labour Office may not, in these circumstances, give protection.

The hazard most in the public eye at present is that due to ionising radiations It is not only workers *in atomic plants that are exposed*, powerful X rays and radium are used to detect flaws in metals, radium paint is still used for luminising, and the X ray plant in the shoe shop can be a source of danger to the assistants who operate it

Most of these industrial hazards are now fully understood, and much has been done to protect workers, indeed Professor LANE thinks that few ells using this method of washing. In the pre- ary trials, "sludging" has been absent or slight, it can almost certainly be entirely eliminated by r regulation of the rate of inflow of blood relative e rate of rotation of the flask. The volume of blood h can be successfully washed by this technique will etermined largely by the size of the conical flask. sk of one litre capacity has been found adequate for processing of one pint of blood in about $2^1/_2$ hours.

vestigations are now in progress to determine the num speed of rotation and optimum rate of inflow. application of this method to blood that has been ed for a long time is also being studied. The washing aratus is being modified in an effort to permit sterile essing of the blood.

SUMMARY

he principle of the "long traverse centrifuge" has n applied to the removal of glycerol from blood- erol mixtures.

n apparatus based on this principle has proved a essful means of removing glycerol in preliminary ls on fresh blood.

WESTMINSTER HOSPITAL, LONDON

HE method of producing deliberate hypotension during esthesia by the injection of pentamethonium or xamethonium bromide has now been in use at this spital for four years (Organe 1950). Various workers ve presented detailed reports of the technique (Davison 50, Enderby 1950). Following our own ended experience certain limitations d disadvantages of these drugs have ome apparent.

1. In order to ensure an adequate fall in od-pressure and to provide a really dry erative field it is advisable to give one large tial dose of the hypotensive drug. Repeated aller injections are less effective; it seems at the patient becomes increasingly resistant subsequent doses. In subjects who are sitive to these agents the large initial dose ay lead to prolonged and excessive depres- on of the blood-pressure.

2. Very young subjects and thyrotoxic tients are resistant to the effects of penta- ethonium bromide. Either the fall in blood- essure is inadequate, or the duration of the potension is very brief. As noted above, peated doses do not solve this problem; tisfactory hypotension cannot be obtained such subjects by increasing the dosage.

3. Although induced hypotension can be ded by injections of pressor agents, this oes not indicate a direct physiological versal. True recovery is complete only after e, occasionally tardy, elimination of the ypotensive drug.

In 1949 Randall et al. described a new anglionic blocking agent. This compound d-3, 4-(1′, 3′-dibenzyl-2′-ketoimidazo- do)-1, 2-trimethylene thiophanium *d*-camphor-sulphonate; it is known by the code number Ro 2-2222 or the trade name 'Arfonad.'

Sarnoff et al. (1952) have used this drug to produce graded reduction of arterial pressure in the treatment of acute pulmonary œdema. A single intravenous injection of 0·2 mg. per kg. body-weight produced a prompt and brief depressor response lasting about three minutes. Tachyphylaxis did not occur when repeated doses were given. The drug was therefore administered in a continuous intravenous drip. Different degrees of reduction in the arterial pressure were obtained according to the rate at which the drug was administered. Cessation of the infusion was followed by prompt recovery of the arterial pressure. Nicholson et al. (1952) have reported on the intravenous administration of arfonad during surgical anæsthesia.

RESULTS

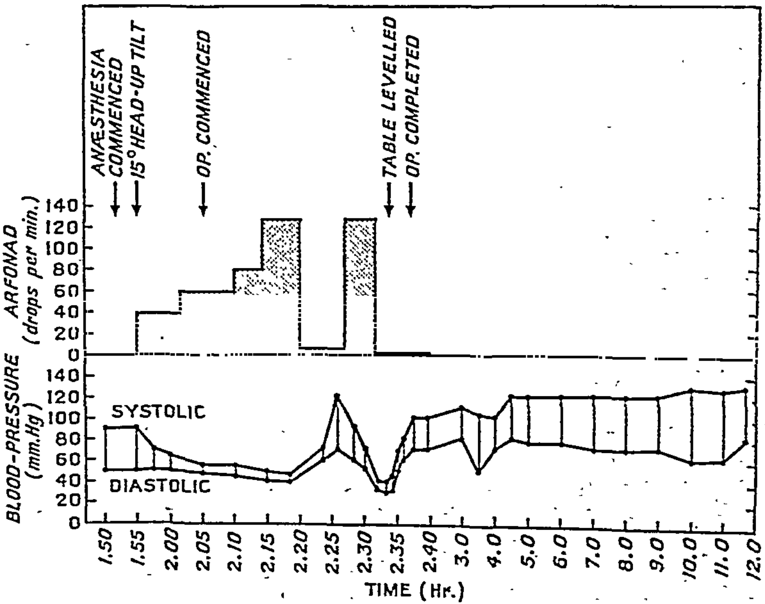
Recently we obtained a small supply of arfonad; and we have given this in intravenous drips to produce controlled hypotension during anæsthesia in 5 cases, as follows: (1) stellectomy, (2) radical mastectomy, (3) laminectomy, (4) thyroidectomy, and (5) mastoidectomy.

The drip solution contains 1·0 mg. of arfonad per ml. The drug is given at the rate of approximately 3 mg. per minute. As shown from the observations in case 1 (see figure) the blood-pressure level is readily controllable by varying the rate of drip. After the drip was stopped recovery was rapid, and the blood-pressure remained very stable during several hours' postoperative observation. In every case highly satisfactory results were obtained. No undesirable side-effects or complications have been observed.

DISCUSSION

So far our results lead us to believe that in arfonad we have an agent suitable for the production of hypotension in a manner that is readily controlled and which overcomes the disadvantages of the methonium compounds. Should these early hopes be confirmed, arfonad will probably supplant other agents for producing controlled hypotension.

Elsewhere close parallels can be seen in the evolution of safer and more efficient techniques by the introduction of agents which are rapidly eliminated. Thus, with



Arterial blood-pressure in case 1 during and after intravenous drip containing arfonad (1 mg. per ml.), with the drip calibrated at 15 drops per ml. Anæsthetic: *thiopentone* 0·5 g.; succinylcholine chloride ('Scoline') 100 mg.; endotracheal intubation with nitrous oxide/oxygen and a trace of trichlorethylene.

gangrene necessitates resection of the bowel—in the past decade it has fallen from over 80 to 23 5% Resection has been most successful when completed by an anastomosis between the ileum and the transverse colon Ileoascending-colon anastomosis has invariably proved fatal There seems to be no particular advantage in the Mikulicz type of two-stage exteriorisation procedure, which should be reserved for patients in a very poor condition Concomitant appendicectomy is advised by LAWRENCE and ULFELDER but condemned by WANSBROUGH and CRAM, who had 2 deaths after leakage from the stump of the appendix In any case this procedure does not prevent an enterocolic recurrence More than forty years ago, at St Mary's Hospital, London, STANSFIELD COLLIER carried out the following routine

> Under anæsthesia, and on the operating-table, through a small catheter inserted into the anus normal saline was allowed to flow in from a height of 2 ft A small incision was made in the right iliac fossa With the aid of one finger in the abdomen the reduction of the intussusception was assisted Reduction might be complete, and always the ileocæcal junction was pulled out of the abdomen and inspected to see if this was so

This combined procedure may be the best There is less shock than if distension alone is relied on, the operator makes certain that it has been effective, and it can be carried out through a small incision. If resection should prove necessary it is a simple matter to enlarge the incision These children always have very mobile colons, which can be easily drawn out of an incision in the iliac fossa

Clinical statistics on the efficacy of any particular form of treatment are seldom very reliable Until we know far more of vital processes and can control them, these *problems are not really susceptible of* exact mathematical analysis Hence the surgeon must, on the evidence before him, decide for himself what course he shall pursue

Annotations

RADIOLOGY IN HÆMATEMESIS

IN this country radiological examination is used almost routinely in the diagnosis of perforation or obstruction of the gastro-intestinal tract Its use to define the source of bleeding from the upper part of the tract, in the acute stage, is much less favoured The reasons for this wariness are broadly two Firstly, one of the accepted principles of hæmostasis is to avoid all unnecessary movement, and it has been thought that the transport and disturbance of the patient that are necessary for a reasonably good barium series may provoke or prolong the bleeding that menaces the patient's life Secondly, in many centres the treatment of hæmatemesis or melæna is still usually expectant and supportive, and thus the exact cause is, for the moment, of secondary importance In recent years, however, improvements in supportive, anæsthetic, and surgical techniques have led to a move towards radical treatment in cases of hæmatemesis thought to be "bad risks" The mortality in elderly patients with chronic peptic ulceration who have had severe or recurrent hæmorrhage is high Avery Jones[1] for example, reported a mortality of over 20% in patients over 70 years of age, compared with one of 2% in patients under 45 years It is in this group of patients with continuing or recurrent bleeding that radiology may help, provided that the examination does not impose too great a risk Such an examination may, in the first place, discover cases that are unsuitable for any emergency surgical procedure, by demonstrating œsophageal varicosities, a large hiatus hernia, or extensive malignant disease of the stomach or upper small bowel More positively, it may reveal the site of a resectable lesion, such as a duodenal or gastric ulcer or a simple tumour

As early as 1937, Hampton[2] described what he regarded as a safe method of demonstrating radiographically bleeding duodenal ulcers, in selected cases Zamcheck et al[3] have now described a study on the safety and reliability of radiological diagnosis in 123 patients, ranging in age from 13 to 88 years, in whom a barium series was carried out soon after massive bleeding from the upper gastro intestinal tract This series included 93 patients who were examined less than three days after admission to hospital, at least 50 of these had a hæmoglobin level under 27%, and all required transfusions In the first 52 cases examined elaborate precautions were taken in handling the patients, both during transport from the ward to the radiological department and during the examination itself, but, in the light of this experience,[4] the more elaborate precautions were discontinued. Preparation for examination consisted in blood transfusion until the hæmoglobin level was 28% or higher, and starvation for twelve hours Examination was postponed when there had been gross hæmatemesis or fluid melæna earlier in the day, when shock was obviously present, or when the patient could not cooperate The result was unsatisfactory in 4 cases, in only 3 was the patient not examined in the erect position, but the routine technique was modified in about two-thirds of the total In 98 cases the initial radiological diagnosis was later confirmed in 25 this initial diagnosis was incorrect or no satisfactory diagnosis was reached After examination 10 patients showed evidence of further slight bleeding, 12 more had severe bleeding, but 8 of these were bleeding at the time of examination Of the 12 who bled severely after examination, 6 were operated on with 2 deaths, the remaining 6 were treated medically, and 2 died

Zamcheck et al believe that there is no evidence for or against a connection between radiological examination and subsequent hæmorrhage, but they feel that the investigation need not be hazardous They are perhaps influenced by the fact, stated by them, that half of the patients admitted to their hospital with massive gastro-intestinal hæmorrhage are chronic alcoholics In their experience hepatic cirrhosis is a common cause, and œsophageal varices were found in 5 cases Gastritis figures rather prominently in their diagnostic summaries —5 times as a single diagnosis, 35 times in multiple diagnoses—and they comment that this, *too*, may be associated with the high prevalence of chronic alcoholism in their cases During the period of their first 52 examinations they saw 12 further patients with severe hæmatemesis who were too ill to be examined radiologically these comprised 3 who were immediately treated surgically after œsophageal varices had been excluded, 6 with hepatic cirrhosis who died without recovering enough to be examined, and 3 without cirrhosis who died within twenty-four hours despite repeated transfusions

Zamcheck and his associates have stated a good case for more liberal use of radiology for early diagnosis in cases of hæmatemesis or melæna There is always a hard core of such cases in which nothing right can be done, and radiology may perhaps help *to reduce* this group the contents of one ampoule are dissolved in 20 ml. sterile isotonic sodium chloride solution, and injected the pleural cavity through an intercostal catheter, which the fine end at other times drains under water. Digestion is then allowed to proceed for about eight s, after which the products of digestion are removed during the next sixteen hours by applying suction of cm. of water by a Stedman pump. Large partly digested particles can be washed from the pleural cavity with physiological saline just before the next dose of streptokinase and streptodornase is given.

For infections of soft tissues a similar solution of the enzymes may be used. The wound is filled with the solution and then covered with 'Nylon' gauze. If the wound is deep, catheters are placed into its depths, a piece of nylon invaginated into the area over the catheters, and the area packed with ordinary gauze. The enzyme is then injected through the catheters. Applications are repeated once or more times daily according to the severity of the infection.

'Lubafax,'† a water-soluble base, has proved a useful vehicle for streptokinase and streptodornase in the treatment of superficial infections. 300,000 units of streptokinase, 75,000 units of streptodornase, and 0·5 g. of crystalline aureomycin are dissolved in 5 ml. of physiological saline solution; and 30 ml. of lubafax is added. The suspension retains its potency for about one week when stored in a refrigerator.

The effects of the enzymes in the treatment of osteomyelitis are improved by the use of a 1 : 1000 aqueous solution of benzalkonium chloride as a solvent, instead of physiological saline solution. Another addition to the chemical treatment of osteomyelitis is a 1% solution of acetic acid in glycerin. Dilute acetic acid dissolves collagen; and glycerin lowers surface tension and aids penetration by acetic acid.

For the treatment of osteomyelitis we suggest a round-the-clock schedule. At 8 A.M. 4 ml. of a 1% solution of acetic acid in glycerin is injected into the wound through the catheter. At 12 noon the wound is irrigated with physiological saline solution. Immediately afterwards and again at 4 P.M., 8 P.M., midnight, and 4 A.M. 4 ml. of the solution of streptokinase, streptodornase, and aureomycin in aqueous benzalkonium chloride is injected into the wound. At 8 A.M. next day the wound is washed with physiological saline solution, and the cycle is repeated. The acetic acid may be used more frequently if necessary; in which case it is substituted for one of the applications of streptokinase and streptodornase.

VARIOUS USES

The causative organism of the infection does not affect the action of the enzymes. Infections due to all of the bacteria commonly found in surgical infections and those due to the gas-forming anaerobes, the tubercle bacillus, *Blastomyces dermatitidis*, actinomyces, and *Histoplasma capsulatum* have been treated successfully.

The micro-organism isolated from the wound will determine the choice of chemotherapeutic or antibiotic agent to be given systemically. Aureomycin may be used topically, since sensitivity to this is rare. The sulphonamide compounds and penicillin should not be used topically, because of the high incidence of induced sensitivity.

Of 85 cases of wounds and infections treated with streptokinase and streptodornase, excellent results were obtained in 80.[11] Of the 5 failures 3 were in cases where gangrene was so far advanced, and the blood-supply so poor, that the action of streptokinase and streptodornase was inhibited. 1 failure was in a case of osteomyelitis where infection in a bone-flap of the skull could not be controlled and it had to be removed; removal of the bone resulted in prompt healing. The 1 failure among the soft-tissue infections was in a patient with severe infection in an advanced carcinoma of the head and neck.

Osteomyelitis

Excellent results were obtained in 30 out of 44 instances of pyogenic osteomyelitis.[13] Of the failures 7 were in patients with gangrene of the lower extremity, which is a definite contra-indication to the use of streptokinase and streptodornase. The 27 cases with a good vascular system included 7 failures. In all of these 27 cases the general condition of the soft tissues improved, but the underlying disease did not heal. When most of a long bone is involved with osteomyelitis, not all the infected bone can be removed, because of the need to retain continuity; and the inability to saucerise to healthy bone then prevents a good result from treatment with streptokinase and streptodornase. In another case similar caution in debridement about a joint led to failure. 2 further cases were classed as failures arising from the patients' lack of care of the area after their discharge from the hospital.

Tuberculosis of Bone

Excellent results were also obtained in 13 out of 15 patients ill with tuberculosis of bone. This group included 8 patients with tuberculosis of the vertebral column; in the 2 failures the local condition of the wound improved but the patients died of progressive systemic tuberculosis.

Pilonidal Cysts with Abscess

Abscesses in pilonidal cysts have also responded well. In 16 such cases the enzymes were applied locally for a period before incision and drainage. These patients, who had to be retained in the hospital until healing was complete, were discharged after an average of 33·7 days. This figure contrasts sharply with the 60–90 days usually lost by such patients in hospitals of the U.S. Armed Forces during the late war. (The number of man-days lost in the U.S. Army during the war from pilonidal cyst and its complications has been estimated at about 3,470,000.[4])

Hæmothorax

Streptokinase and streptodornase are extremely useful in the treatment of hæmothorax, since the fundamental need in the treatment of this complication is the removal from the pleural cavity of clotted blood, fibrin, and cellular debris to permit prompt re-expansion of the lung. Treatment should be started as soon as bleeding is controlled. 12 patients have been treated with excellent results.[17] In 11 of these cases the date of onset was known; and treatment was started, on average, slightly more than eight days after injury; in 3, however, the interval was well above the average, and in 1 of these it was as long as twenty-six days. Radiological evidence of slight pleural thickening or a small amount of pleural fluid was found in each case at the time of discharge, but such residua usually disappeared in the succeeding months. This method is applicable to battle casualties. The operation is simple and can be done with few instruments in a forward area. It does not preclude air evacuation.

Tuberculous Abscess

Many surgeons are reluctant to drain tuberculous abscesses because they fear secondary infection. In 19 cases, however, where streptokinase and streptodornase were applied, no secondary infection ensued.[18] These cases included 4 of tuberculous empyema, 5 of tuberculous lymphadenitis, and 10 of tuberculosis of bone, joint, or tendon. In 16 of these cases, the tuberculous infection was controlled and all wounds and sinuses healed. The remaining 3 patients had advanced and progressive tuberculosis; in each there was local improvement, but the systemic tuberculosis led to death.

Tuberculous empyema with bronchopleural fistula has to be treated with care, since thinning of the pus may promote spread of the infection.

---

† Manufactured by Burroughs Wellcome & Co. Inc.

a combination of the effect on the blood-vessels and the direct action on the nerve cells [2] Meigs and Hughes add that severe cases may also show abnormal respiratory signs, such as dullness, râles, and rhonchi, and skin lesions ranging from circumscribed erythema to ulceration and dry gangrene, commonly at pressure sites The heart may also be damaged, probably because its rate of working and its need for oxygen are great [2] The degree of permanent residual damage in any organ is directly related to the duration of unconsciousness, further emphasising the necessity for speedy treatment

CEREBRAL SWELLING

Two patients may have apparently identical cerebral tumours, and yet in one there is only a local neurological disturbance while in the other intracranial pressure is high and there may be signs of a tentorial pressure cone Atkinson,[4] discussing this problem, considers that the contrast may be due to differences in cerebral swelling in the two cases He uses the term to mean any increase in brain volume, however small, and prefers to confine the term "cerebral oedema" to a condition where there is an increase of fluid in the interstitial tissues of the brain The volume of the brain varies to some extent under physiological conditions—for example, during respiration At the end of inspiration the brain seems to recede from a dural defect, and at the end of expiration it swells towards the defect, and, as O'Connell[5] emphasised in 1943, this respiratory variation is probably an important factor in the normal circulation of the cerebrospinal fluid There is also pulsation of the exposed brain with each heart beat, and this small alteration in cerebral volume is increased when the systemic arterial pressure rises In animals a greater proportion of carbon dioxide in the inspired air, and to a lesser degree a reduction in the oxygen content, will also cause an increase in cerebral volume[6], and a similar effect can be seen in a brain exposed at operation if there is a temporary failure of oxygen-supply Atkinson says that obstruction of cerebral veins near the superior sagittal sinus in man results in cerebral swelling in the area normally drained by these veins, and he bases this opinion on the swelling visible in the adjacent gyri when a vein is occluded during craniotomy On the other hand, Beck and Russell[7] were unable to demonstrate cerebral oedema in experimental animals after division of cerebral veins near the sagittal sinus

Atkinson's thesis is that these mechanisms are of importance in the production of brain swelling in a patient with a cerebral tumour cerebral veins may become occluded, with swelling of the adjacent gyri, and arterial occlusion may develop, leading to damage to the capillary endothelium in the infarcted area, pooling of blood, and transudation of fluid through the capillary walls The brain swelling produced in these ways may in turn lead to tentorial and other pressure cones, and these in themselves may further increase the cerebral swelling When part of the temporal lobes herniate through the tentorial opening the cisterna ambiens may be occluded, obstructing the free circulation of the cerebrospinal fluid and disturbing the normal equilibrium between the cerebral venous blood and the cerebrospinal fluid When this happens, anything which suddenly raises the intrathoracic pressure, such as an attack of coughing, may cause serious cerebral venous congestion with further brain swelling, and Atkinson considers that this is an important cause of serious tentorial coning Herniation through the tentorial opening or the foramen magnum may also cause occlusion of branches of the basilar artery, supplying the brain stem, or the posterior cerebral arteries, supplying the occipital lobes, and effects may again add to the cerebral swelling

Atkinson makes out a good case for the importance of brain swelling in the manifestations of intracranial tumours and for the vicious cycle which may result once swelling has started, but he leaves us still wondering why gross swelling may develop in association with only one of two apparently identical tumours

"VISCO-ELASTICITY" OF LUNG

EVERYONE who has seen a rubber balloon or a tin of treacle knows in a general way what is meant by the terms "elasticity" and "viscosity" it is when we attempt to measure these properties that we run into trouble Nor is there much disagreement about their importance in the living body Even those of us who could not look a poise in the face are aware that blood is thicker than water, and that the viscosity of the blood-stream is thought to have a physiological as well as a rheological significance As for elasticity, like Macaulay's schoolboy we all know the distribution of elastic fibres in the body, and, perhaps rashly, assume that they confer elasticity on the tissues with which they are associated Some of our illusions are, however, being undermined The "spring" ligament, whose very name begs the question, springs no more, for it has been shown to consist only of white fibrous tissue with no elastic fibres[1] On the other hand, the auricle and the nose continue to return to their original shape so long as they are not subjected to excessive violence, and the *ligamentum nuchæ* can be stretched to 140% of its length and return to its former dimensions

We are accustomed to cite the lung as an elastic organ, when it is no longer sucked outwards by the negative pressure in the pleural sac it recoils inwards and collapses This collapse takes place in life when the intrapleural pressure is raised, or, as McIlroy[2] has shown, after death, a considerable volume of air is expelled from the chest in the first two or three hours after death When, however, we attempt to relate this "elastic" behaviour of the lung to the physical law propounded by Hooke—to which, as McIlroy points out, no known material conforms—we find that the lungs behave as a "visco-elastic" system rather than a purely elastic one In a viscous system the response to a force depends on the time for which the force is applied, while in an elastic system the response depends on the magnitude of the force, systems giving intermediate results are called visco elastic The visco elastic behaviour of the lung has been established for dead material by McIlroy and Christie,[3] who measured spirometrically the response of the lung to variations in the pressure within a lung plethysmograph On occasion there was a time lag of several minutes before equilibrium at a given pressure was reached, and a predictable response was obtained only when small pressures were applied repeatedly, as in ordinary respiration The lung is thus not a purely elastic organ, a viscous factor is present Because of the time taken to reach equilibrium, the volume of the tidal air in simulated respiration varies inversely with the rate of this respiration McIlroy and Christie have used the relation of the tidal air at 3 "respirations" per minute to the tidal air at 15 "respirations" per minute as an index of the viscous resistance of the lung This index, they found, increased with the age of the patient from whom the lung was derived, and they suggest that what is usually called "loss of pulmonary elasticity" is really an increase in lung viscosity In ten emphysematous lungs the viscous resistance was increased, and it was shown that this was not due to any significant bronchial obstruction

ENYLBUTAZONE (BUTAZOLIDINE) IN THE TREATMENT OF CHRONIC ARTHRITIS

L. CUDKOWICZ
M.D. Lond.
REGISTRAR

J. H. JACOBS
M.A., M.B. Camb., M.R.C.P.
SENIOR REGISTRAR

E RHEUMATISM UNIT, ST. STEPHEN'S HOSPITAL, LONDON

E introduction of phenylbutazone (butazolidine) e management of rheumatoid arthritis (Currie 1952) been followed by discussions of its "antirheumatic" ts and its toxicity (Hart and Johnson 1952, on et al. 1952, Crowther and Elgood 1952). This r describes our experience in the first 50 cases of nic joint disorder treated with phenylbutazone in hospital.

any of these patients were attending the routine cs of the rheumatism unit, and detailed laboratory stigations were not always possible.

he duration of treatment with phenylbutazone ged from four months to a few days, and some patients ived a total dose of as much as 73 g. The daily was varied according to the response of the patient, never exceeded 1 g. per day. Oral preparations have become available during the last five months, and re this, daily intramuscular injections were used.

RESULTS OF TREATMENT

umatoid Arthritis

henylbutazone was given to 34 patients with imatoid arthritis.

bjective results.—Objective results of treatment were ssed in terms of

) Grip (mm. Hg.).
) Range of movement (in degrees).
3) Swelling of joints (circumference in mm.).

20 patients (59%) there was objective improvement, luding reduction of joint size in 6 but in 12 (36%) improvement could be demonstrated by these ndards. The other 2 patients became worse and e swelling of their joints increased.

Subjective results.—19 patients (56%) considered themselves improved, and 4 of them were in fact able to walk again; 2 (5%) thought that they were worse; 5 (15%) noticed no change in their condition; and 8 (24%) became free from pain, 2 of them were able to discard a calliper and crutches respectively.

Effects on erythrocyte-sedimentation rate.—Changes of less than 5 mm. were ignored. In 9 patients (31%) the E.S.R. (Westergren) fell; in 11 (38%) there was no significant change; and in 9 (31%) it rose.

Ankylosing Spondylitis

In the 3 patients with this disease who were treated, subjective and objective improvement occurred in 1, and there were no changes in the other 2. The E.S.R. rose in 2 and remained unchanged in the other.

Osteo-arthritis

The 11 patients with this disease were treated in the same way as those with rheumatoid arthritis. Objectively, 7 patients improved, as judged by increase in power and range of movements. The other 4 patients remained unchanged. Subjectively, 8 patients experienced relief from pain, and of these, 5 became free of pain altogether, including 1 patient who was also suffering from Paget's disease.

Other Conditions

A patient with spondylolisthesis, who was severely disabled by low back pain, was sufficiently relieved to return to work.; and another with tendonitis of the shoulder, had less pain and more movement.

SIDE-EFFECTS

Side-effects developed during treatment in 22 (44%) of the 50 patients. The side-effects encountered were:

Abscess at site of injection	3
Gastro-intestinal symptoms	6
Reactivation of peptic ulcer	2
Melæna	2
Salt and water retention with œdema ..	8
Rashes	5

The abscesses were sterile and required incision. Healing was delayed for three months in one instance.

The patients who had gastro-intestinal symptoms included 4 who were having phenylbutazone by mouth. One patient was able to continue treatment when the dose was reduced from 1 to 0·6 g. daily, and the other 3 were relieved by Mist. Mag. Trisil. Co. *B.P.C.* However, in 2 patients treatment had to be stopped. In 2 patients with histories of peptic ulcer, there were recurrences—in one case fourteen years after the original episode.

A patient who had been having oral phenylbutazone for two weeks, and another who had had 17 g. by injection over seventeen days, became rapidly anæmic and dyspnœic, and developed cardiac failure. Their Hb levels dropped from 92 to 69% and from 102 to 52% respectively. These patients subsequently had massive melæna, but without appreciable gastro-intestinal upset. Hæmorrhagic effects had not been encountered before and coagulation-times and platelet-counts were not measured.

In 3 patients who showed evidence of salt and water retention, there was a significant fall in urinary chloride output in the early stages of the development of œdema. In 2 patients œdema was controlled with mersalyl, and in one case treatment was continued with both mersalyl and phenylbutazone for twelve weeks in view of the considerable clinical improvement.

Of 5 patients who developed rashes, 4 were first affected in the second week of treatment and 1 in the fourth week. The way in which the drug was given seemed to be of no significance. The prodromal symptom in each case was severe pruritis, which was followed in one instance by a pyrexia of 103°F. A severe facial urticaria and a morbilliform rash appeared in 1 patient. After these eruptions faded, they were followed by a petechial rash and the development of splenomegaly. The clotting-time was prolonged to 7 minutes (normal 4–5

Public Health

DECEMBER FOG IN LONDON AND THE EMERGENCY BED SERVICE

G F Abercrombie
M D Camb
CHAIRMAN, EMERGENCY BED SERVICE COMMITTEE,
KING EDWARD'S HOSPITAL FUND FOR LONDON

In the first half of December, 1952, a violent and untimely "epidemic" smote the people of London, and applications to the Emergency Bed Service (E B S) for the admission of general acute cases far exceeded all previous records In what follows, E B S admissions only are considered, there must have been a great number of direct admissions of which the E B S has no knowledge

Fig 1 shows day by day the applications for this month of December (7992 applications, 6852 [85 73%] admitted) compared with those for the previous August (2946 applications, 2815 [95 53%] admitted) Plotted thus, the graphs are too erratic to be of use in predicting how many requests the service is likely to receive in the immediate future, but if, instead, a "moving" weekly total is calculated and charted, the more extreme irregularities disappear and the general trend becomes discernible Fig 2 shows the moving weekly totals each winter from 1949 to December, 1952 Each point on these tracings shows the total applications received during the previous seven days for example, the weekly total up to Nov 30, 1952, was 1313, and next day 243 applications were received, adding these and subtracting the 220 received on Nov 24, the moving weekly total for Dec 1 is 1336

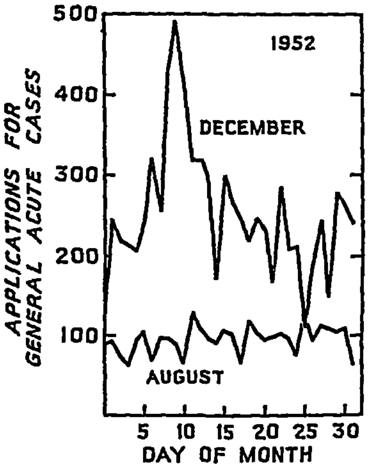

Fig 1—Totals of daily applications for admission of general acute cases in August, 1952, and in December, 1952

The annual rhythm is now fairly clear After a quiet summer the line begins to move upwards as winter approaches, there is usually (though not in 1951) a characteristic fall just at Christmas, and then the line rises steeply to its peak in early January, after which it declines more or less steadily to reach the summer levels in April

WARNING SYSTEM

After January, 1951, when 7064 applications were received and only 65 5% of patients were admitted, the service evolved a warning system which is now on trial When the percentage of admissions to applications, calculated on the moving weekly totals, falls below 85%, a "white" warning is sent to the appropriate hospital authorities This is a precautionary signal, saying in effect "E B S is hard pressed and may be in serious difficulty in the next day or two" If the percentage falls below 80% a "yellow" warning is issued, and if below 75% a "red" warning These are urgent calls for help and mean "The situation is serious, the resources of E B S are rapidly being exhausted, and for one patient in five—or four—no bed can be found" On receipt of these warnings, regional-board hospitals take prearranged action to provide more accommodation by slowing down admissions from the waiting list putting up extra beds, and so on Teaching hospitals also informed and cooperate as far as possible

THE FIRST YELLOW WARNING

In 1952, owing to the prevalence of cold weather early November the work of the service rose st throughout that month with the result that on D 243 general acute applications were received in the normal 130 or so This rise continued until D when the fog settled on London, and the numb

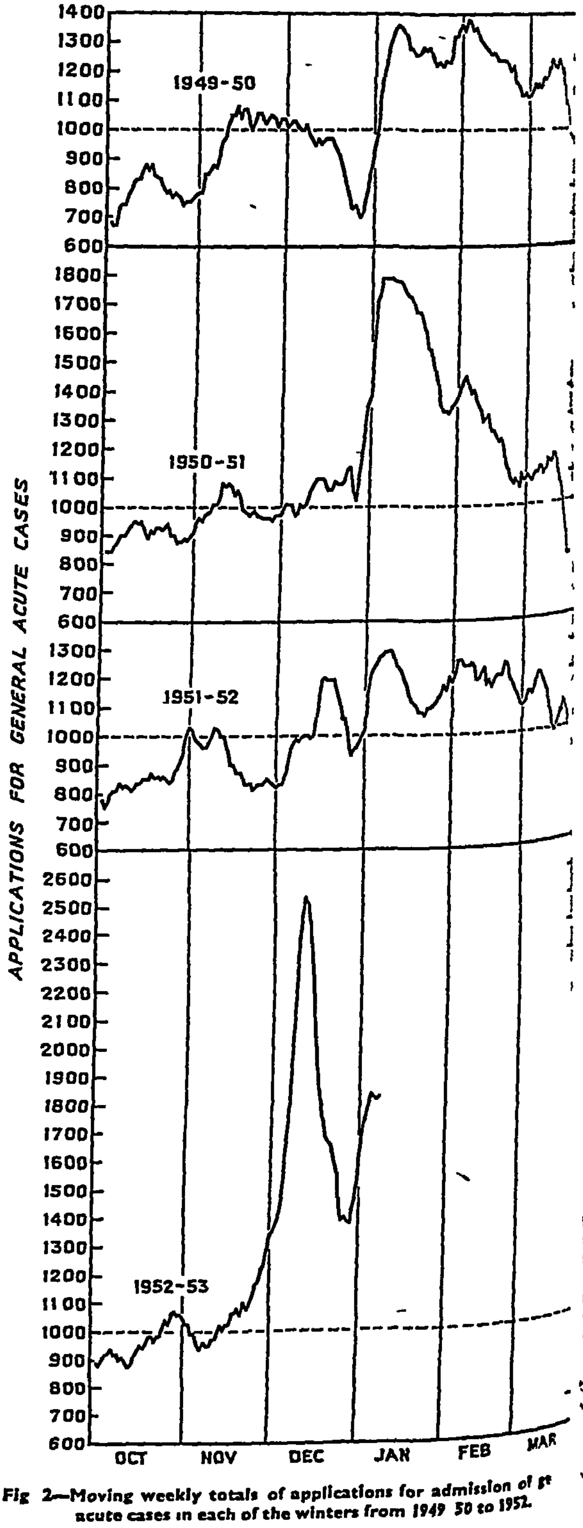

Fig 2—Moving weekly totals of applications for admission of ge acute cases in each of the winters from 1949 50 to 1952

Reviews of Books

al Radiology of the Ear, Nose, and Throat

RIC SAMUEL, M.D., F.R.C.S., F.F.R., D.M.R.E., late hon. adiologist, Middlesex Hospital, London. London: I. K. Lewis. 1952. Pp. 339. 70*s*.

TIL the appearance of this book there had been no cation in this country wholly devoted to the logy of the ear, nose, and throat. Dr. Samuel has ght together the best recent writings on the subject, 1 have hitherto not been easy of reference, and he lso kept the anatomical and clinical aspects well to ore. For each region there are chapters on the logical techniques employed, and on the develop- and anatomy of the structures. These are followed hapters on the normal and abnormal radiological arances and the clinical features connected with . This arrangement has resulted in some repetition, ially of anatomical material. The style, moreover, t easy and there are some errors which would not escaped more careful editing. The illustrations numerous but their quality is varied. On the r hand, the full references, and the indexing, both uthors and subjects, suffice in themselves to make ook valuable.

land's Forceps

E. PARRY JONES, M.B., M.R.C.O.G., consultant obstetrician and gynæcologist, St. Asaph General and Maternity Hospitals. London: Butterworth. 1952. Pp. 212. 35*s*.

OUT half this book concerns forceps in general: the inder describes the Kielland instrument, its design nanufacture, the indications for its use, the technique plication, the dangers, and the results that may be cted. Mr. Parry Jones has used the instrument on ccasions, and from careful personal observation and l review of the literature he gives a detailed and useful unt of the place he thinks the instrument should hold iodern obstetric practice. There is a translation in ppendix of the original article by Christian Kielland hich his forceps and his special method of insertion described. The book is beautifully illustrated and ly read; it will certainly revive interest in an obstetric eps which has never achieved the popularity in this ntry which it holds in Scandinavia. The instrument ers considerably from the more usual forceps, and iy useful and important technical details are described Mr. Parry Jones, which will undoubtedly help others ise the instrument with judgment and skill. On the er hand, some of the statistical tables and many of illustrations (especially of other types of forceps and hose who have designed them) might have been left . They make the book much more costly than it d have been.

icer Cytology of the Uterus

J. ERNEST AYRE, M.D., director, Dade County Cancer Institute, Miami, Florida. New York: Grune & Stratton. London: J. & A. Churchill. 1952. Pp. 407. 105*s*.

To the few in this country who practise cytological gnosis of uterine carcinoma by smears this new book ll be of interest. It is an atlas of 362 figures accom- nied by full, though often discursive, descriptive gends, and a text of some 53 pages interspersed with ges of figures. Based on 150,000 preparations—vaginal iears, cervical cell smears, and cervical cell scrapings—om over 22,000 women, the work is a cytomorphological udy chiefly of epidermoid carcinoma of the cervix. tological findings in cancer of other sites in the female nital tract, in certain benign conditions, and in normal iears are also given. Such topics as the organisation the service, the technique of taking and preparing ecimens, and the method of reporting on smears are cluded.

There is much in "gynecytology" and in this book iich is disputable and open to serious criticism. urticularly is this true of what Dr. Ayre calls "nearo- rcinoma" ("the precancer cell complex": "incom- etely developed carcinoma cells"), which lies at the art of the problem and on which the chief value of iear diagnosis depends. To quote the author, "when adequate scientific data are available to prove the specific character of the anaplastic precancer cell of the cervix, a significant advance in knowledge of carcinogenesis will have been achieved." Adequate scientific data have yet to be provided.

Congenital Dysplasia of the Hip Joint and Sequelæ

VERNON L. HART, M.D., F.A.C.S., assistant professor of surgery, University of Minnesota. Springfield, Ill.: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1952. Pp. 187. 36*s*.

IN this small book Dr. Hart makes an appeal for the earlier recognition and treatment of the dysplastic hip-joint; the pleasant style and beautiful production make it well worth reading. Although few cases of frank congenital dislocation escape skilled orthopædic care in this country nowadays, there is still a vast amount of avoidable disability in the form of subluxation and osteoarthritis secondary to lesser degrees of unrecognised dysplasia. Because simple abduction treatment in the infant can prevent all this, early recognition is of cardinal importance; and Dr. Hart clearly describes the separate clinical and radiographic signs, all minor in themselves but adding up to a convincing total picture, which must be looked for.

Comparative Biochemistry of the Carotenoids

T. W. GOODWIN, D.SC., F.R.I.C., senior lecturer in the department of biochemistry, University of Liverpool. London: Chapman & Hall. 1952. Pp. 356. 50*s*.

THE carotenoid pigments are widely distributed in plants and animals, and are sometimes present in micro-organisms. Except when they are concealed by other pigments, such as chlorophyll, their intense yellow colour always makes their presence obvious. Research on their physiological importance has resulted in prolific studies of the function of carotene as provitamin A, but little else has been clearly established. We have no adequate explanation, for example, of the tendency of carotenoids to be concentrated in the reproductive organs of animals and plants.

In writing this comprehensive account of the distribution of carotenoids in all forms of living tissues, Dr. Goodwin has not only worked hard to collect information, but has spent much time in constructive thinking. Information from a wide field has been cleverly condensed, often into tables. The two main parts of the book deal with carotenoids in plants and animals, and attention is focused on current theories which give hopes of explaining their biological functions and on possible lines of future research. Though the book as a whole has been written primarily for biologists and biochemists, parts of it are of considerable medical interest—especially those on the distribution of carotenoids in the tissues and blood in health and disease, and on the factors controlling the conversion of carotene to vitamin A.

Three Vesalian Essays

SAMUEL W. LAMBERT, WILLY WIEGAND, and WILLIAM IVINS, jun. New York: Macmillan. 1952. Pp. 128. $6.00.

MOST of the wood blocks used to illustrate the original editions of Vesalius's *De Fabrica* and *Epitome* were found in 1932, in the library of the University of Munich; unfortunately they perished during the late war. In connection with their discovery these three important essays were written.

Dr. Lambert describes and reproduces the drawings used for the initial letters of the first two editions of *De Fabrica*. These show anatomical and surgical subjects in which the acting parts are taken by young children, a conceit which heightens their artistic merit. Dr. Wiegand, of Munich, gives an account of the discovery and history of the blocks, and also some interesting points about the title page of *De Fabrica* and the continuous landscape which forms the background to the twelve muscle men in that book. The charm of the book vanishes with the third essay, by an art-expert who admits he has no knowledge of anatomy or Latin. Smooth reading is lost by the inclusion in the text of bibliographic details and lengthy bracketed material which should have been printed as footnotes. In the main the essay is a sustained attack, not always in good taste, on the Vesalian writings of Dr. Charles Singer—which are described as careless, lacking in exactness,

TABLE II—AGE DISTRIBUTION OF RESPIRATORY DISORDERS

Age	0–4	5–9	10–19	20–29	30–39	40–49	50–59	60–69	70–79	Over 80
No of patients	—	3	—	1	—	2	8	13	12	4

Digestive Disorders

6 patients were seen during this period with sudden attacks of vomiting This came on at the peak of the fog, and it was not accompanied by other digestive disturbance, such as abdominal pain or bowel alterations Presumably the cause was gastric irritation produced by swallowing fog

Respiratory Disorders

It was here that the fog produced its most serious effects 43 patients, with varying degrees of illness, were seen with signs of involvement of the lower respiratory tract They very often gave a history of previous chest trouble in 37 of these patients there was a history of either recurrent productive winter coughs and dyspnœa—i e, chronic bronchitis—asthma, bronchiectasis, or one of the forms of pulmonary fibrosis In this practice there are 105 people with these chest troubles, and 37 of them were affected

The *age distribution* is shown in table II, which shows how the elderly suffered most

The *sex-distribution* showed a 2 1 preponderance of men, there being 29 men and 14 women in this group

The majority of the illnesses had a fairly sudden onset on the third or fourth day of the fog This latent period has been noted during other fogs, and it may be due to the fact that by the third or fourth day the concentration of atmospheric contaminants reaches a certain threshold level, or it may simply be that it takes this period for the respiratory defences to be overcome The symptoms and signs seemed to arise from a combination of

(1) Mucosal irritation (cough and sputum)

(2) Bronchial obstruction (dyspnœa, cyanosis, and loud rhonchi during both inspiration and expiration)

(3) Infection (fever and general constitutional upset—probably a secondary factor superimposed on the local irritation)

(4) Cardiac failure (evident in many of the more elderly patients)

On clinical assessment, 16 patients were severely ill, with considerable distress, and in some danger, the other 27 had only a moderate degree of dyspnœa and general disturbance Quite a number of these were able to remain up and about in their homes, and some even went out to work

The severe cases were medical emergencies with paroxysmal dyspnœa, accompanied by an irritating and distressing cough and blackish mucopurulent sputum Cyanosis was obvious in some patients, and in all of them the pulse-rate was around 120, the respirations were between 35 and 40 per minute, and the temperature varied from 100° to 104°F

There were loud rhonchi all over both sides of the chest in both phases of respiration Râles were noted in some cases, especially after a few days' illness In no case were signs of clinical consolidation detected The picture was therefore one of severe asthma, if asthma is taken to mean a condition of dyspnœa produced by bronchial obstruction, but these patients did not respond to the usual antispasmodics

It was impracticable to carry out any radiological or pathological investigations there was so little time and so much work

Most patients improved slowly and it took four to nine days for the symptoms and signs to clear up This course was not influenced in any obvious way by the treatment adopted This was directed to controlling the infection by using antibiotics—procaine pen the first instance and chloramphenicol if there wa improvement after four days—and to attempt relieve the bronchial obstruction with antispa such as adrenaline, ephedrine, isoprenaline, and a phylline, whose effects were at the most very short The less severely ill were not treated with antib but with simple hot saline expectorants, combined antispasmodics It was not possible to use oxy these cases

Of this group of 43 patients, 2 died and 1 was adm to hospital A man, aged 66, with a past hist pulmonary fibrosis which had caused great dis for some three years, died within four hours of onset of symptoms An old lady of 76, who had a severe pneumonia four years previously, which left her prone to winter coughs and dyspnœa die the eighth day of illness from cardiac failure The pat admitted to hospital was an elderly man, who was ill to be nursed at home by his even older wife

CONCLUSION

These observations agree with the analysis the effects of the November fog of 1948[1] effects of a fog, in association with cold weather, principally on the respiratory and gastric mucosa Irritative symptoms, such as cough, nasal discharge and vomiting, are the primary results, but in ch respiratory invalids secondary infection and complications often appear in the lungs and bron The most severe cases are found in the elderly, being rare under the age of 45. It is remarkable that although there are quite a number of asthmatic children in this practice none of them was affected, in fact, th *was less illness than usual in children during this* The same observation was made during the influe epidemic of 1950–1951, when there was wide illness in adults but less than usual in children

Influenza

Last week reports of widespread influenza on Continent and in the United States were quickly follow by news of large numbers of cases in this count especially in the south of England There is so no evidence that the disease is taking a severe and recovery from the acute symptoms within 48 h seems usual In some patients the respiratory sympt have been followed (not accompanied) by gastro intestin disturbance Early laboratory evidence suggests an A-prime virus is responsible

The latest figures from the 160 great towns of En and Wales show 72 deaths from influenza in the ended Jan 17, compared with 51 in the preceding There were 76 deaths from influenza in the great in the corresponding fortnight of 1952 Deaths pneumonia showed no significant increase up to Jan Notifications of pneumonia (primary or influen in England and Wales numbered 1204 in the week Jan 17, compared with 1107 in the preceding week 869 in the corresponding week of 1952

These figures give no indication of the rapid spread mild influenza that is taking place One doctor on outskirts of London reports that Monday, Jan. was his heaviest day in 15 years of general prac On Jan 27 the Emergency Bed Service issued a " warning to hospitals This warning is given when service finds that London hospitals can take less t 75% of the cases referred to the service for adm Regional boards have asked their hospitals to resp to this warning by bringing into action plans for restr ing the admission of non-urgent cases and for fre as many beds as possible

On the Continent epidemics are reported in Fra and Germany (where the U S zone is particular affected) An influenza vaccine has been distrib for the inoculation of American troops in Europe

THE LANCET

LONDON: SATURDAY, JAN. 31, 1953

The Patient in His Hospital

> "It is difficult for those who are familiar with hospital life to realise just how incomprehensible and alarming hospital routine appears to the outsider."

ifficult indeed; for as we cross the hospital threshold ır rhinencephalon responds to the familiar odour of lish and medicaments with a host of pleasing sociations: here we have enjoyed work and comnionship in wonderfully stimulating surroundings. or the patient it is otherwise. If he has been to ospital before it was in a mood of anxiety, either ild or severe, and possibly he suffered discomfort or ain: such memories colour his emotions at a second isit. If he has never before been to hospital his npressions are coloured by both anxiety and fear of ne unknown. The Central Health Services Council, n the memorandum[1] from which the above quotation s taken, warn all who work in hospitals of the danger f thinking of patients as "cases," and identifying hem as—for instance—"the duodenal in the first ed on the left." The atmosphere in hospitals which are for people, they say, is profoundly different from he atmosphere in hospitals which deal with cases: nd they add that here the general hospitals have something to learn from the mental hospitals, in which "there is no mistaking the atmosphere of genuine interest and sense of community which greets the patient and which helps him towards recovery."

A patient should be able to count on the help and friendship of his hospital: and especially since it is nowadays his hospital indeed. He has, for instance, a perfect right to ask questions and expect courteous replies; and, in fact, as the council point out, he will respond much more readily to sensible explanations and requests for help than to instructions delivered in an autocratic spirit. In hospital today the patient often encounters a string of specialists, each examining some aspect of his bodily function—and each engrossed with his own specialty. The story of the expert who put a needle into a vein, and only noticed when the blood failed to flow that the patient had no further need of his services, is possibly an invention; but undoubtedly doctors do, from time to time, arrive at a bedside bearing alarming equipment, and set about their humane purposes without so much as a "good morning," let alone a "by your leave." This is not what they would wish to befall their young children or their old mothers, or possibly even their wives (though doctors' wives are notoriously equal to anything); and they would certainly not lie down under such treatment themselves.

Akin to such ill-manners is the practice, still strangely prevalent, of discussing the patient's more alarming symptoms, across his bed, with a class of students, or of withdrawing to a short distance and saying in a penetrating whisper: "Of course we can't say when the next catastrophe will come: it may be in six years—or six days." The patient naturally wants to learn what to expect, but not through unwilling eavesdropping, or in terms which nibble at his self-confidence—or even devour it altogether in a single ill-considered mouthful. The council note (as we have often done) that there is a widespread feeling among patients and their relatives "that they do not receive enough information either about the nature and probable course of their illnesses or about its implications for their family and business affairs." Their questions should be answered kindly and clearly, and the council hold that they should have access to the medical staff in order to put them: each patient, indeed, should be told whom to consult and when. At visiting times the ward-sister or her deputy should be available—and on view—to answer visitors' questions and to have a word with those who have come long distances. Telephone inquiries, too, should normally be answered by the sister or her deputy; and the character of her reply, as the council are careful to point out, can do much to make or mar happy relations with the relatives. They wish to impress not only on doctors but on all who work in hospitals that good relations cannot be regarded as a natural growth. "They require cultivation, and will only be attained if everybody who comes into contact with the patient, from the consultant to the charwoman, regards it as part of his or her job to produce them."

Consideration, and understanding, of the patient's point of view should operate even before he is admitted. As soon as his name is put on a waiting-list he should be sent a letter giving him any information he and his relatives need while he is waiting for a bed. A second message, telling him the bed is vacant, should also be sent in a letter, for a postcard bearing the name of the hospital may betray the nature of his complaint to others. Many hospitals nowadays give the newly admitted patient a brochure describing the work of the hospital and the part it plays in the life of the community, and reminding him that he is going to be looked after by people with a tradition of service behind them. It also tells him what amenities are provided: the library, the newspaper round, the services of a hairdresser, the telephone facilities, the arrangements about smoking, the visiting days. The names of visiting chaplains, and the times of services of the different denominations, are also given; and it may be worth mentioning here a point not mentioned in the memorandum: old people, and people in chronic wards, are often much helped by the visits of ministers of their religion, yet because long-stay hospitals are often large, the minister (who usually has a parish or other appointment to serve) cannot possibly visit them as often as he and they would like. There is a good case in such large hospitals for the appointment of whole-time chaplains.

General practitioners who are interested in this type of teaching are asked to notify the secretary of the college, as soon as possible, as to the ways in which they are willing to help in these teaching schemes

Postgraduate Instruction —The college will encourage and help practitioners to accept postgraduate instruction

This will need close coöperation with the British Postgraduate Medical Federation of the University of London, whose director has put aside a room for this purpose at his headquarters (2, Gordon Square, London, W C 1) It has been suggested that the college's regional faculties shall, in a similar way, work in close liaison with the postgraduate deans and directors of the eighteen other universities—Aberdeen, Belfast, Birmingham, Bristol, Cambridge, Cardiff, Cork, Dublin, Durham, Edinburgh, Galway, Glasgow, Leeds, Liverpool, Manchester, Oxford, St Andrews, and Sheffield

This postgraduate instruction can be of several kinds—attendance at hospital outpatient departments or at medical society meetings, lectures, half-day courses, weekend courses, 5½ day courses (from Monday to Saturday), and courses lasting a fortnight or longer For the last four of these courses, most National Health Service practitioners are allowed grants paid by the Ministry of Health (fees, subsistence and travelling allowances), and for the last two, payment of a locum tenens may also be approved

Practitioners are asked to notify the secretary of any suggestions they may care to make about this postgraduate instruction—where and when they think it can most conveniently take place in different districts, and what are the subjects in which they feel they most want help

Research in General Practice —The encouragement of accurate observation, investigation, and recording of results by general practitioners is to be an important part of the work of the college

The research committee of the college wishes to establish a register of members and associates of the college who are interested in the possibilities of research work in their practices It is hoped that this register will provide means of introducing to one another practitioners who share common research interests, to enable them to pool and exchange their ideas and information

A panel of experienced practitioners, and workers in other fields of medicine and science, is being formed to advise and help not only groups of doctors but also individuals who may wish to carry out research work by themselves in their own practices A number of investigations will be initiated by the college itself, and study groups are to be set up throughout the British Isles Methods of collection of this material by practitioners will vary, and will be designed to throw as little strain as possible on the routine work of each day Cards and flimsies suitable for these investigations, and which will fit the N H S envelopes, may be printed.

In order to explore the possibilities of coördinating research by large groups of general practitioners, it has been suggested that an " Investigation of the Year for General Practitioners " might be undertaken Suggestions are invited about the possible nature and scope of such an investigation

Members and associates are invited to apply to the secretary if they would like their names to be placed on the research register Applicants are asked to state any particular research interests they may have, and whether they would be willing to participate in group-studies

All suggestions made to the college on these subjects are to be carefully considered and analysed , and a report upon them will be published later The deans of many medical schools, the director of the British Postgraduate Medical Federation of the University of London, the postgraduate deans and directors of other universities, the Medical Research Council, and many university research departments have expressed their interest in these proposals, and have agreed to advise and to help in their possible development

Points of View

DAILY PAPER PANTHEON

A NEW FANTASIA OF THE UNCONSCIOU

ALAN McGLASHAN
M C, B A Camb, M R C S, D P M
PSYCHOTHERAPIST TO THE WEST END HOSPITAL AN
ST GEORGE'S HOSPITAL, LONDON

MILLIONS of adults read the comic strips in the papers Those who do not are amused, baffled exasperated by those who do Unhappily addicts either dumb (in both senses) or evasive, and there seem able to give valid reasons for their semi secret It is a minor sociological mystery, inviting minor

Even a first glance shows something interesting strips for adults, an offshoot from children's comic are not homogeneous they fall into two main One is simply a tabloid version of the every thriller The other, distinguished always by an of the miraculous or magical, has an attraction compulsive, altogether different

Examples of this second kind occur everywhere, strangely, by far the clearest were to be found till in a single newspaper, the *Daily Mirror*, where no than four of the six comic strips unmistakeably to it—three of them on one page

CONTEMPORARY MYTHS

Garth and Jane, Jimpy and Captain Reilly Ffo it possible that someone on the staff of the *Daily* chose these grotesques with full understanding of he was doing ? It is wildly unlikely Yet beyond and the even less likely explanation of pure cha there lies only one other possibility—that they chosen by the uncannily accurate processes of un scious selection, operating at the deepest level of human psyche If this were so, they would be *to exert a curiously compulsive power, overriding* ra repudiation, on the minds of multitudes Which precisely what they do

For these figures are no casual products of the ima tion Faintly through all their exploits, vulgar puerile as these usually are, sounds an echo of some unimaginably archaic the adventure cycles of the gods Kerenyi, latest among many, has shown with probability that such adventure cycles are the themes of human mental activity as far back as it ca traced They recur endlessly in the likeliest and unlikely places, the noblest and most degenerate forms

Consider *Garth*, that beefy and bewildered giant, suffering, virtuous, strong, faced by a never ending of heroic tasks Is there not more than an echo here Hercules and his labours, much-enduring far travel Ulysses, blinded Samson, Noah, Gilgamesh and be all these the timeless image of the heroic principle in aided magically by Heaven in reward of faith and val

As for the often excruciating *Jane*, beautiful virginal, constantly wooed but never wed above —far, far above—does there not float, as on vau ceilings of Venetian palaces, a company of bright figu Hainuwele the moon-maiden, irresistible Helen, Ap dite from the wine-dark sea, flower gathering Perseph and the countless images of Kore the maiden god La Belle Dame sans Merci, the unpossessable yet e nally nubile she, whose golden promises invest with brief splendour the too credulous heart of man not *Jane* in Fritzy the dachshund even poss appropriate animal attribute, as Diana has her ho and Cynthia her hare ?

In *Captain Reilly-Ffoull* the echoing image is at o more immediate and more remote His life of sham gusto, full of shady triumphs and richly earned hu dustrial workers are exposed to as great a hazard the nurse who is looking after a patient who is being eated by radium. A great deal of work is naturally eing done on the best method of supervising workers xposed to radiation, so that they can be removed rom exposure before irreversible damage is done to heir bone-marrow; and this work is not made easier y the fact that the ill effects are liable to appear ong after the exposure. At first efforts were directed o carrying out frequent blood-counts, especially white-cell counts, on all workers, even if the exposure was only slight. It is now clear that normal variation s so wide that such counts are not helpful; nor are outine six-monthly counts really effective. The present view seems to be that where the total internal and external radiation does not exceed 10% of the maximum permissible level, routine blood examinations are unlikely to help; better protection may come from the wearing of a "film badge" which measures the exposure of the whole body to radiation. For workers exposed to higher levels of radiation the total and differential white-cell counts seem likely to give the most satisfactory protection.

There have also been moves to improve the protection of lead workers. Lane[5] has faith in the punctate-basophil count, provided it is done under standard conditions. The possibility of using the coproporphyrin excretion in the urine as an early index of lead intoxication has been explored, but Lane's experience is that this varies too much from case to case for a "danger level" to be agreed on; he prefers the direct estimation of lead excretion in the urine.

Examination of the blood is necessary for the control of many industrial hazards. The larger concerns have their own hæmatological laboratories; but smaller businesses cannot afford the expense, and the responsibility then falls on the local factory doctor, who may or may not have access to a hospital laboratory for prophylactic blood-counts. Professor Lane emphasises that blood-counts have their limitations and that they are only one method of finding out whether toxic substances are causing damage, so that too much reliance should not be placed on them alone; this applies especially to single counts at long intervals. Potentially dangerous compounds are being increasingly used in industry, and the industrial medical officer has to be constantly vigilant. It would, of course, be better to investigate the effects of potentially dangerous substances before they are brought into general use than after they have been found to poison industrial workers.

Intussusception

The resolution of biological problems is seldom easy; for very few of the multifarious activities of living cells are fully understood. As it is impossible to devise a test with only one variable, crucial experiments are almost unknown. If this is so when experimenting on single cells, how much more true it is in clinical work, where the observer is dealing with a whole organism and is not free to vary conditions at will. It is hardly surprising that, despite careful observation, there are continuing doubts as to the relative merits of surgery and medicine in duodenal ulcer and in Graves's disease, and of surgery and radiation in malignant disease. We do not even know whether it is better to apply heat or cold to inflammatory processes.

Such thoughts are provoked by three papers on the diagnosis and treatment of intussusception.[1–3] Intussusception is a mechanical disorder that is influenced by vital reactions. The inconstancy of the symptoms bears witness to the variability of the primary biological material. Thus Lawrence and Ulfelder,[1] who report 53 cases, say it is disturbing to find that there was no history of pain in 5 of the 6 younger patients with gangrenous bowel, nor in 3 babies with non-gangrenous acute intussusception. In adults there was always a history of pain, and the disease developed much more slowly—in more than half over a period of 9 days or more. Vomiting was noted in nearly all the children but in only half the adults. In half the children and in nearly all the adults there was no bleeding from the bowel. On the other hand, Wansbrough and Cram[2] found bleeding in 85% of 575 cases. Lawrence and Ulfelder detected a palpable mass in half the children but in only a third of the adults, whereas Wansbrough and Cram found a mass in 84%. Neither pair of workers mention a characteristic feature in acute intussusception—namely, that the mass disappears between the attacks of pain, when the bowel wall is relaxed, and reappears when a peristaltic wave causes it to harden. Lawrence and Ulfelder remark that between attacks the children appeared well, whereas the adults "reflected more truly the abdominal disease." These two workers noted resistance of the abdominal wall in the absence of a mass in two-thirds of their patients, adults and children. But in babies it is the very relaxed abdomen between the spasms of pain that often obscures the diagnosis. Lawrence and Ulfelder found in one-third of the patients a definite suggestion of intussusception by a simple abdominal radiograph which showed absence of cæcal gas, often with an associated soft-tissue mass; dilated loops of bowel were seen only late in the disease. A barium enema proved a valuable diagnostic aid.

Both groups of workers warmly advocate operative treatment; whereas Nelson,[3] of Sydney, and Lindberg and Morales,[4] of Sweden, extol conservative methods. Nelson uses for reduction hydrostatic pressure of 3 ft. of saline solution under complete anæsthetic muscular relaxation; success is indicated by uniform distension of the abdomen. Of 102 intussusceptions in patients under two years of age, 43 were completely reduced by this method. By the Scandinavian method a radio-opaque enema is given and the intussusception reduced under screen examination. This was done successfully in 18 consecutive cases. With surgical treatment the mortality has been much reduced in recent years, partly through the aid of chemotherapy. Lawrence and Ulfelder had no deaths in 28 cases of non-gangrenous intussusception treated by simple reduction. Wansbrough and Cram report a mortality of 5·2% in 575 cases, including those requiring resection. The reduction in mortality has been most striking in cases where brought before the Courts previously because of the expense of litigation

He agreed with Lord Merthyr that probably the right way to tackle this problem was at the start, and not when it was halfway down the hill He did not underestimate the importance of attempting conciliation in suitable cases, and he was sure that the marriage guidance councils were doing valuable work On these grounds it might well be argued that not only ought the cuts to be restored but that a good deal more money ought to be given to the marriage guidance councils But the amount of aid which the State could give depended on the economic circumstances of the time Again, if marriage guidance councils were to do any good they must be voluntary services He did not believe that they would receive the same public confidence if they were in any way a State organisation But if they were to remain voluntary services there must obviously be a limit to the amount of financial aid which they could receive from the State Thirdly, marriage guidance was still in its infancy, and the methods of counselling and attempting reconciliation were still to a great extent experimental The Marriage Guidance training board were inquiring into the selection and training of counsellors Their findings would be helpful in assessing the progress so far made The Harris Committee, which had recommended that Government grants should be made to these councils, had suggested that the grants should be for an experimental period of five years That period ended in the financial year 1953–54 Present arrangements would have to be reviewed next year, and he assured the House that full weight would be given to what had been said in that debate about the importance and value of the councils' work

QUESTION TIME

Hospital Block Grants

Mr **Peter Roberts** asked the Minister of Health whether he would consider the possibility of allowing hospitals to run their block grants over a spread of five years, in the same way as universities were financed —Mr **Iain Macleod** replied. The annual amount involved would be for Great Britain some £280 million I think that, apart from other considerations, a sum of this magnitude must be examined each year by the Government and by Parliament

Atmospheric Pollution

Replying to a question, Mr **Macleod** said that there were 15,114 deaths registered in Greater London in the five weeks ended Jan 3, 1953, compared with 9125 in the corresponding period a year earlier Figures for the country as a whole were not yet available, but there were 34,764 deaths registered in the 124 great towns in the five weeks ended Jan 3, 1953, compared with 25,821 in the corresponding period a year earlier The only relevant figures of hospital admissions available were of those arranged by the Emergency Bed Service in Greater London these were 6852 in December, 1952, and 4300 in December, 1951 While a large part of the increases in Greater London could be attributed to fog, the trend of the figures for deaths did not suggest that the fog caused any substantial increase in the rest of the country

Lieut Colonel **Marcus Lipton** asked the Minister what representation his department had on the Atmosphere Pollution Research Committee, and whether he had notified the committee that 4703 persons died in the Greater London area during the week ending Dec 13, 1952, as compared with 1852 during the corresponding week of 1951, a large part of which increase he had attributed to the fog —Mr **Macleod** replied My department is not represented on the committee, but I have confirmed that the committee are aware of the figures quoted

Lieut-Colonel **Lipton** Will the Minister see, as a matter of urgent priority, as the fog in December, with its man made atmospheric filth, killed thousands of people in the London area, that his department is represented on this committee and will take the most vigorous steps in association with the departments concerned, to reduce this appalling and unnecessary loss of life, which in the light of the figures that he has mentioned—6000 more deaths in five weeks in London—is on the scale of mass extermination ?—Mr **Macleod** My department has been looking into this matter as a problem of the very greatest urgency, as I agree it is, but this committee is mainly a scientific body concerned with causes, whereas, for obvious reasons, I am far more concerned with effects I think that the method that we are adopting—there is a between this committee and the M R C —is a better

Mr **P J Noel-Baker** Will the Minister give consideration to the granting of a subsidy to the Smoke Abatement So —Mr **Macleod** I will look into that suggestion.

Butazolidine in Rheumatism

Mr **Edward Evans** asked the Minister if he would statement on the claims made in respect of the drug 'Butazolidine' as a cure for rheumatic ailments including rheumatoid arthritis —Miss **P M Hornsby-Smith** replied The of this substance is still under investigation in this Current evidence suggests that in view of the possibility undesirable toxic side effects it should not be taken under medical direction

Mr **Evans** Is it not in the highest degree undesirable cruel that the lay press should spread among the public most extravagant claims causing false hopes in regard cure of this disease ? Is it not possible to call the attention of the press to the need for caution in the publication of statements until some authoritative announcement has made ?—Miss **Hornsby-Smith** I agree whole heartedly it is most undesirable that hopes should be raised with to drugs which are not yet wholly proven

Prescriptions at Child-welfare Clinics

Mr **Gerald Williams** asked the Minister if he arrange for doctors at child welfare clinics to give prescriptions which could be exchanged for medicine under National Health Service —Miss **Hornsby Smith** replied It is for the family doctor to issue any necessary prescription The clinics exist to give advice and not medical treatment There would be a very real danger if patients were able treatment in the clinics when they might also get treatment from their own doctors That would only create and might be dangerous

Capital Expenditure on Hospitals

Mr **Wilfred Fienburgh** asked the Minister what was estimated capital expenditure on hospitals in 1950-51 England and Wales compared with the capital expenditure 1937–38 after allowing for changes in the price level Mr **Macleod** replied About £9 million compared about £17 million

Bone-conduction Hearing-aids

Replying to a question Mr **Macleod** said that hundreds of bone conduction aids had been supplied patients taking part in clinical trials The bulk supply on order should begin to reach distribution centres within next few weeks, and he hoped there would be enough to most, if not all, of the expected demand for about England and Wales

Anthrax

Replying to a question, Sir **Thomas Dugdale**, Minister Agriculture, said there were 382 and 730 cases of anthrax involving cattle in 1951 and 1952 respectively Anthrax this country was mainly caused by the use in feeding and fertilisers of contaminated imported materials It seldom practicable to identify the particular ingredient responsible, but there was little doubt that imported products, such as bone meal, were a fairly common source infection As a first step the Ministry of Agriculture now discussing with the appropriate trade associations measures to reduce the risk from this source Until the discussions had been concluded, he would be reluctant take any action which might substantially reduce the quantity of feeding stuffs and fertilisers available in this country An effective vaccine against anthrax had been used number of years under the supervision of the Ministry veterinary staff, but only for animals known to be exposed particular risk of infection During 1952, vaccine sufficient to vaccinate about 13,000 cattle or twice as many pigs issued The vaccine had now been made available generally to veterinary surgeons for use at their discretion, but it too early to say to what extent its use would increase the new arrangements Generally, the vaccine had good results

Antibiotics for Livestock

Sir **Ian Fraser** asked the Minister of Health if he amend the Penicillin Act, 1947, to provide that antibiotics might be used for the treatment and feeding of livestock especially pigs —Miss **Hornsby Smith** replied The Government propose to introduce a Bill on this subject shortly

TOXICITY OF STREPTOMYCIN AND P.A.S.

THE treatment of tuberculosis calls for administration potent substances for long periods; and it is thus pecially important to know the smallest effective daily se of these agents. With streptomycin it has been und that 1 g. daily can replace the 3 g. that used be given; and thereby the incidence of toxic reactions s been much reduced. Similarly intermittent dosage streptomycin has proved effective against the less ute types of the disease or after daily administration s reduced toxæmia. Fewer injections are an advantage, so, to the nursing staff, for the risk of a nurse developing in sensitivity to streptomycin depends partly on the umber of injections she gives. This cutaneous sensitivity, hen it develops, is persistent; and those affected may ven have to abandon tuberculosis work. In patients, ith the reduced dosage and the purer forms that are ow marketed, streptomycin causes comparatively few rious complications; even vertigo seems to be much ss common. Dihydrostreptomycin, it is true, occasionlly gives rise to deafness; a survey by the research ommittee of the British Tuberculosis Association[1] suggests that such disasters will be rare if the daily dose does ot exceed 1 g., but perhaps on the whole dihydrotreptomycin is best avoided except as a local application or tuberculous empyema, where it seems to act more ffectively than streptomycin,[2] though even here a ourse should not exceed 20 g.

In general we can now feel easier about administering treptomycin; but increasing experience has done othing to allay anxiety about the risks with its usual artner—*p*-aminosalicylic acid. Originally its only rawbacks were thought to be alimentary disturbance and the unpleasant taste of the drug; but now they are nown to be many. Some of the most serious reactions are due to the development of drug hypersensitivity. Pyrexia, skin rashes (including exfoliative dermatitis), and liver damage have been reported increasingly often; and associated effects include hypopotassæmia, hypoprothrombinæmia, eosinophilia, cardiac arrhythmia, myxœdema, anuria, mental confusion, glandular enlargement, and splenomegaly.[3] Nor is this all; for hypersensitivity, when it occurs, may not be to P.A.S. alone but also to other substances which contain a phenol group with an amino radical in the para position—for example, certain sulphonamides, picric acid, and even hair dye.[4] The allergy may be still more general; for P.A.S.-sensitive patients have reacted adversely to the subsequent administration of streptomycin and penicillin. Clearly this drug, though relatively innocuous to many, produces profound disturbance in some. The nature of this disturbance is by no means clear, but there is much evidence that the endocrine system is intimately involved; in particular there are indications that the pituitary, the thyroid, and the suprarenal are affected, and it is also significant that A.C.T.H. will overcome the allergy due to P.A.S.[5]

Pugh et al.[6] have lately described 7 cases of psychosis with onset during treatment with sodium P.A.S. They suggest that this complication was due primarily to salicylate stimulation of the pituitary gland. The tuberculous infection, they believe, created the original non-specific stressor, the additional stressor being sodium-P.A.S. stimulation of the pituitary with consequent hypercorticoidism and associated mental confusion. When the phase of pituitary stimulation was followed by pituitary exhaustion and hypocorticoidism, a paranoid reaction ensued. In each case other conditioning factors were present—for instance, sustained resentment and hysteria before the tuberculous illness, an unhappy love affair in a patient with an over-dependent personality, and long-continued domestic worry—but, according to Pugh et al., the common additional stressor factor, with one possible exception, was sodium P.A.S. According to these workers, the tubercle bacillus thrives in an environment characterised by depressed thyroid activity, a relatively active adrenal, and an actively functioning gonad; they further suggest that, in addition to its recognised bacteriostatic effect, P.A.S. may owe some of its therapeutic success to its ability to correct hormonal imbalance in tuberculous patients.

Even if the explanation by Pugh et al. is not wholly correct, their work seems to point the way to more direct hormonal treatment of tuberculous disease. Already success is claimed for A.C.T.H. (given in association with streptomycin and P.A.S.), not only in overcoming hypersensitivity due to chemotherapeutic agents but also in other cases where lesions have not responded to more orthodox measures. We may be on the verge of an era when chemotherapy will be supplemented by hormonal therapy.

CARBON MONOXIDE POISONING

CARBON monoxide, the commonest suicidal and accidental poison, has two possible modes of action. The better-known one is its displacement of oxygen, and its alteration of the oxyhæmoglobin dissociation curve. Less well known, and said to occur only with high concentrations of the gas, is its interference with the cytochrome-oxidase system in any tissue. The affinity of carbon monoxide for hæmoglobin is more than 200 times that of oxygen, so that a concentration of carbon monoxide $^1/_{200}$ of that of oxygen in inspired air would eventually reduce the oxygen-carrying power of the hæmoglobin by 50%; and such a mixture would be dangerous if breathed for long. Like simple oxygen lack, the effects of carbon monoxide on respiration are slight until the subject is on the verge of collapse, so that he may not realise he is in danger until it is too late. Haldane[1] noticed no remarkable symptoms when his blood was one-third saturated with carbon monoxide.

Accidental poisoning usually arises from partial combustion of fuel or leakage of coal gas or exhaust gas; and leakage of carbon monoxide in aircraft can be particularly serious. Experienced pilots know that one of the earliest signs is loss of brightness perception and of fine coördination of the ocular muscles.[2] With slow cumulative poisoning, the effects include weak and aching limbs, an increased pulse-rate, frontal headache, and nausea. If enough carbon monoxide has been inhaled to cause collapse, a number of after-effects may develop; and Meigs and Hughes[3] have lately analysed the different effects of mild, moderate, and severe poisoning in an attempt to find which signs are of prognostic value. They confirmed the observation that mental relapse after apparent recovery is of serious significance. In severe poisoning the commonest findings were abnormalities of the nervous system, lungs, and skin, excessive sweating, a palpable liver, pyrexia, a tendency to bleed, a high white-cell count, and albuminuria. In the human central nervous system oxygen lack seems to damage the globus pallidus most readily.[2] Clinical and experimental evidence has not yet identified the exact function of the globus, though it is known to be concerned in the smooth and coördinated movement of voluntary muscles: hence, perhaps, the frequency of spasticity and tremor in carbon monoxide poisoning. Cerebral cortical damage and profound demyelination are also seen at necropsy, and they are probably due to

Letters to the Editor

POLIOMYELITIS

SIR,—Your leading article of Jan 10 is surely unfortunate In it long-tried orthopædic principles are rejected, although no new information is produced in favour of such rejection, and in addition there are a number of confusing contradictions

Thus we read, without any evidence being adduced in support of this reversal of established principles, that "in the care of muscles and joints no rigid splinting, plaster casts, or orthopædic frames should be applied even in the acute stage", instead, "passive movements and maintenance of a neutral position by simple means, such as sandbags, footboards, and pillows are the best remedies" It is also stated that "trick movements should not be discouraged" although four lines above is the recommendation that "the *patient should* be spending most of the day exercising the weak muscles and not the strong" During the period of active treatment trick movements offend not only, as you say, the "well-trained" physiotherapist but also anyone familar with the consequences of early subordination of the weakest to the strongest muscles—which subordination is unavoidable in performing trick movements

You give as fact that deliberately induced fatigue does not harm the paretic muscles and that immediate active vigorous exercise to the point of fatigue will give maximal muscle recovery in a matter of weeks rather than months or years, adducing the testimony of Mead[1] (in fact wrongly) and Ritchie Russell[2] *in support of your views* and saying that Ritchie Russell has failed to confirm that deliberately induced fatigue harms the muscle But if we are to judge from the chart which Ritchie Russell uses to illustrate this statement in his book *Poliomyelitis* we are forced to the opposite conclusion We see that the greatest progress made by the patient took place in the first three weeks, when only "ordinary physiotherapy" was given, and that during the subsequent three weeks, when contractions to the point of fatigue were performed hourly for twelve hours every day, there was no progress at all, when, however, the frequency of these repeated fatiguing exercises was reduced to only *four days in every seven improvement re started, though* not at the rate of the first three weeks One might add that we are accustomed to expect more of treatment than that claimed here—namely, that it "does no harm" In fact a more extensive investigation was carried out by Green[3] on two hundred patients divided into three groups He showed that the most constant improvement was obtained by the group of patients kept most at rest, the least by those having most exercise, and an intermediate result by the intermediate group This corresponds better with our knowledge of training of normal muscle in the laboratory and in athletics

It is not my purpose, however, to discuss here the merits or failings of different methods used to improve muscle power, but only to object to the way in which problems still under investigation are presented in your leader as solved Above all, one must deplore the way in which the subject is presented, an example is the statement that "even the severely paralysed should be walking or in a wheeled chair and ready to go home 5–8 *months from onset*" *In such a variable disease as* poliomyelitis the claim that a particular method of rehabilitation will give such rapid recovery as to allow even severely paralysed cases to be discharged from hospital within eight months of their attack may bring transient discredit to centres where some patients are, because of the particular severity and distribution of their paralysis, still struggling after more tha months to overcome their disabilities sufficiently to hospital Some of these patients will need re surgery—e g, tendon transplants and arthrod obtain the maximum use of the muscles which rem them Such a programme cannot possibly be s into the prescribed eight months

Further, I am convinced that if you atter prevent deformity by the methods you advise, a "alternate active movement and rest in the position," the results will not be dissimilar to tho such men as Robert Jones, Vittorio Putti, and Ridlon found thirty or forty years ago before it wa last recognised that a case of paralytic polio presented an orthopædic problem from the beg *It is surely only because in some countries* o Continent orthopædic treatment of poliomyelit not begin until deformity is established that man from abroad are now attending British orth hospitals It would seem paradoxical, to say the that when some of these Continental countr diligently starting to follow the British lead we revert to conditions which prevailed before the ti Robert Jones

KWASHIORKOR

SIR,—*In your leading article of Nov* 29 you co on Kahn's request that the term "Kwashiorkor" be restricted to cases with pigmentary change note that "he seems to be in error (with C Williams)" But if you will refer to your is Nov 16, 1935, when the word kwashiorkor was printed,[1] you will see that there was no reference to literal interpretation of the word, nor was re described as necessary to, though it might be prese the condition It may well be that, as MacPherson s it applies rather to the mystique of the disease and to pigmentation

In your first paragraph you refer to the difficult comparing the disease as it appears to different ob in different countries I have now been able to see of this disease in the Gold Coast, Uganda, Ke Tanganyika, India, Ceylon, Malaya, Thailand, Bu Indonesia, Egypt, and Jamaica—though I have no course been able to make anything like detailed stud It seems to me that there is similarity, although there many degrees of it As you point out, there are as m variations as there are different possibilities in die patterns and accompanying infections and infestatio not to mention individual variations In a country Uganda, where the diet is remarkably standardi ed, disease is much more uniform than in a country Jamaica where there is a much larger variety of po bilities This disease varies greatly in appearan according to the various stages of its development

In recent years the enormous extent of the proble of child nutrition has begun to be recognised Th have been great advances in the investigation of t pathology of nutritional diseases, but little has b done towards their prevention

In England, and in the developed countries in gene the child health services have produced great impro ments The "underdeveloped" countries are tendi concentrate all their efforts on hospitals and dis control programmes These do not of themselves af the standard of living and of education of the pe who are most in need of help *The major cau* mortality and morbidity are not malaria, smallpox, cholera, nor are they surgical conditions They mainly malnutrition, worms, skin diseases, and ga enteritis, which are in fact due to dirt and ignora is work relates only to dead lungs under artificial itions, and in the living body other factors might into play. Nevertheless, these experiments have a iderable interest in relation to respiratory physiology pathology: and, perhaps more important, they rate once again the difficulty of applying simple ical concepts and measurements to biological erial. In any biological system so many influences ract with each other that it is often almost impossible eparate the effect of one of them for study. To call lungs elastic, however satisfactory in everyday versation, is clearly an over-simplification; and such -simplifications can be dangerous.

TECHNIQUES OF VIRUS TYPING

HE merits of different animal sera in typing strains nfluenza virus have long been disputed. Workers in tralia, Holland, and this country have used mainly et sera; while in the U.S.A. rabbit, fowl, and ister sera have been preferred. With ferrets and isters the serum is taken after the animals have been cted with influenza virus, whereas the other sera obtained after immunisation. The argument has more than academic since epidemiological deducs based on results with ferret sera could not have made with, for example, fowl sera. Hitherto the ute has been mainly emotional with each laboratory ly to swear by its own results. Now Sampaio [1] has le a direct comparison between the different sera. chose four strains of influenza virus; one was a ntly isolated A-prime strain, and the others were, logically speaking, a brother, a first cousin, and a y-second cousin. With all the sera tested the distant tive was easily spotted; but the fine distinctions ween the near relations were detected with ferret l hamster sera only. Sampaio's work would appear settle the argument—though if hard facts were to le all arguments this would become a quieter and ler world.

ABSORBABLE GLOVE POWDER

SOME years ago it became clear that contamination of operation field by talcum powder from the surgeon's ves might give rise to serious after-effects.[2] In women clean" appendicectomy was occasionally followed by rility, owing to the reaction of the fallopian tubes to c granules picked up from the peritoneal cavity. perimentally talc applied to the peritoneum gave rise intraperitoneal adhesions and granulomata. Spilling talc glove powder in more superficial wounds also ve rise to non-healing granulomata. These findings l surgeons to wash their gloves in a sterile solution er putting them on, and to discard at once a glove with y defect that might allow powder to escape.

Since this danger was brought to light there has been a stained search for an absorbable substitute for talc a glove lubricant; and corn starch has been widely ed.[3] Lee and his colleagues [4] at Cincinnati suggest at the feeling of security with such powders has sulted in some carelessness on the part of surgeons. eing convinced that they now have a "fool-proof" owder, they no longer observe the precautions they ice did against wound and peritoneal contamination. this lack of caution justified? Lee and his co-workers ave carried out a series of experiments, similar to those hich proved the dangers of talc. From these they onclude that under ideal conditions starch powder is bsorbed without ill effect. Nevertheless, until it is bsorbed it is a foreign body and produces a foreign-body eaction in the tissues. The intensity, duration, and eversibility of this reaction is influenced by many ariables. Complete dispersal of the powder into individual granules is essential, and can be assured by admixture of the starch with either 2% magnesium oxide or 3% magnesium carbonate; the tissues tolerate these two dispersal agents equally well. "Tanning" of the starch with epichlorohydrin renders the starch granules resistant to autoclaving, but does not affect either the tissue tolerance or the absorbability of the starch as long as it is well dispersed in fine particles. "Clumps" of powder imbedded in tissue will produce more reaction and will be absorbed more slowly. The experiments by Lee et al. included heavy dusting of the bowel surfaces of animals with the starch powder; and even with such gross contamination the reaction was relatively slight. Infection of the operation area would, however, greatly increase the foreign body reaction, and might produce unabsorbable adhesions.

The conclusion is therefore that sterilisable starch approaches the ideal as a glove lubricant; that it must be combined with a suitable dispersal agent; and that the surgeon should adopt the simple precautions of washing his gloves just before approaching the operation field and of avoiding spilling deposits of powder through defects in the fingertips of his gloves.

ENZYMES AND TRACHEOTOMY

IT is not easy to maintain a clear airway in patients who have respiratory paralysis due to poliomyelitis or who are unconscious during the treatment of meningitis and head injuries. Repeated aspiration of the pharynx and postural drainage are usually effective for the first day or two, but small quantities of material from the pharynx inevitably find their way into the trachea. So long as the antibiotics are fully effective this is of no clinical significance; but when resistant organisms replace the normal flora of the nose and throat, infection spreads into the trachea.

Tracheotomy will prevent this complication, but it will not relieve it once the tracheal infection is established. The trachea and bronchi then become filled with exudate, and, unless free drainage is provided, death results from a combination of asphyxia and bronchopneumonia. The exudate is mucoid at first, becoming purulent and then mucoid again as the infection subsides. After tracheotomy it tends to dry into tenacious masses and crusts because it is exposed to air unmoistened by passage through nose and throat. Crusting can probably be prevented by providing a fine mist of water or saline for the patient to breathe, but the exudate is still sufficiently viscid to reduce the airway.

Enzymes will liquefy the exudate, and encouraging clinical results have been reported [1]; but they must be chosen carefully, for enzyme action is highly specific. Three constituents can be responsible for the viscidity of a tracheal or bronchial exudate: (*a*) a fibrous gel of mucoprotein during the early and the late stages of an infection; (*b*) fibres of deoxyribonucleoprotein when the infection is fully established and the exudate purulent; and (*c*) fibrin, which is particularly prominent in diphtheria. Simple cytochemical tests are available for the identification of these constituents; the enzyme should be selected accordingly and administered as an aerosol. A satisfactory fibrinolysin is available commercially, but pure deoxyribonuclease and specific mucinases are not. Crystalline deoxyribonuclease from ox pancreas is very effective in liquefying purulent exudates,[2] but the streptococcal nuclease accompanying streptokinase is rarely sufficiently concentrated for this purpose. Lyophilised crystalline trypsin acts rapidly on mucus in solution,[3] but only slowly on mucoprotein gel. Until more specific and pure mucinases and deoxyribonucleases become available commercially, lyophilised crystalline trypsin is probably the best enzyme to use.

faculty might wish to make from time to time The faculty has therefore appointed a committee composed of

Sir Harold Graham Hodgson, Middlesex Hospital (chairman), Dr Hugh Davies, National Hospital for Nervous Diseases, Prof A S Johnstone, Leeds General Infirmary, Dr J W McLaren, St Thomas's Hospital, Dr P H Whitaker, Liverpool United Hospitals, the president and hon secretary ex officio

This committee will study at regular intervals the problems arising out of the units system referred to them by the Ministry

In the light of experience, the faculty will doubtless have sufficient information to enable it to advise the Ministry on the desirability of retaining the scheme with appropriate modifications or replacing it by a more satisfactory scheme

A HARLEQUIN COLOUR CHANGE IN THE NEWBORN

SIR,—We have been interested, since the publication of our article on this subject,[1] to receive letters from twelve mothers in various parts of this country, and one in the United States, describing the same colour change in their own babies, most of whom appear to have been normal mature infants That the condition is no new one is confirmed by the fact that one of the babies in question is now 52 years old and herself the mother of a healthy family

We have also heard from a man who is affected by what appears to be the same colour change at times, particularly during severe exertion in a hot climate

Children's Department,
Royal Victoria Infirmary,

LEG ULCERS

SIR,—The articles in your issue of Jan 3, concerning the stubborn gravitational ulcers around the malleoli, will not I think help us forward very far One is written to support Bauer's contention that ligature of the popliteal vein is a help, but too many have been disappointed with it The second method, of Mr Cockett and Mr Elgan Jones, attempts to do the same thing at a lower level, and this unfortunately involves an incision into the devitalised tissues of the ulcer-bearing area *This incision makes my flesh creep, for I remember* the struggles I have had with ulceration in this area in the scars that have followed operations on veins, injection necroses, excisions of indurated skin treated by Thiersch and even pedicle grafts, and Corlette's Λ shaped incision to stop pain These ulcers in surgical scars seem to be far more stubborn than those in the scars of previous ulcers The tissues of the lower part of the leg from marrow to skin are affected by the high venous pressure, and excisions of skin cannot reach healthy tissues, *so I feel strongly that the golden rule* of no incisions or excisions in this area must not be broken

I do not think that the inveteracy of recurrence of deep venous incompetency is fully realised A study of the excellent phlebograms in Cockett and Jones's paper shows vast venous pools left behind after dealing with the important perforating arteries, and these are bound to cause mischief later

The best explanation of all the phenomena of ulceration of the *leg is provided by* Morgan's theory that the high pressure in the veins opens the skin shunts and capillary circulation fails This explains why some ulcers recur immediately after healing and others may stay healed for years before recurring in exactly same form as previously The high venous p there all the time, but it does not always cause capillary circulation of the skin to fail and there is unknown conducive factor which comes into play

I still feel that the best way to treat these ulcers with elastic adhesive bandage and pads, co operation on the veins to those of the saphenous sy The troubles from deep incompetency are met by of various kinds to prevent œdema and recurrence

London, W 1 A DICKSON WRIGHT

PARTIAL THORACIC STOMACH IN CHILDH

SIR,—I was interested in the article by Dr Car his colleagues[1] on partial thoracic stomach in child Now that so much interest is being taken in this dis all pædiatricians will agree that it is relatively co At the same time I am struck by the larger numb infants with an apparently typical history of this dis who respond most dramatically to the upright po only In these infants a barium swallow shows n appearances, and in particular a normal angle of e of the œsophagus into the stomach with no re the head-down position

I would be most interested to hear if other have found the same, and if so what they regard a ætiology of these symptoms Is the vomiting in cases functional or is it due to a sliding hiatus he If the latter, one would have thought that the an entry might not be normal Should the *term* " cardia," which has now largely fallen into disrepute used to cover these cases?

Plymouth HUGH JOLLY

MITRAL STENOSIS

SIR,—Your annotation on mitral stenosis (Jan 1 deals with only certain aspects of controversial iss

Anatomical and physiological studies by my coll and myself[2] have demonstrated a good correla between the type and severity of symptoms on the o hand, and the severity of the mitral stenosis and pulmo vascular disease on the other Our evidence favour view that progressive valvular stenosis and progres clinical incapacity usually go together We do n concur with Brock that the stenotic mitral valve is al always the same size Mild and moderate stenos observed at necropsy or operation, was usually associ with mild to moderate symptoms We do agree, howev that major symptoms do not result until the valve 20% of normal, or 1 cm in area

While there are admittedly errors in its applicat the hydraulic formula for calculating mitral valve s defines the relationship between heart rate, blood fl and blood-pressure at the valve Variations in b state during cardiac catheterisation may well alter a or all of these factors, but their relation to one anot cannot be changed as this depends on the valve ar Errors in assessing clinical status by physiolog measurements can be avoided if this fixed relationship appreciated

A word of caution is necessary about apical systo murmurs These may be caused by tricuspid as well a mitral incompetence, and mitral incompetence ma exist without a murmur Furthermore, the massive l atrium is more often a sign of mitral incompetence th of stenosis[3], when it is present with mitral steno may well be the *result* rather than the cause of a relativ benign prolonged course Finally, tricuspid insufficie is associated with a " benign " course only in so far

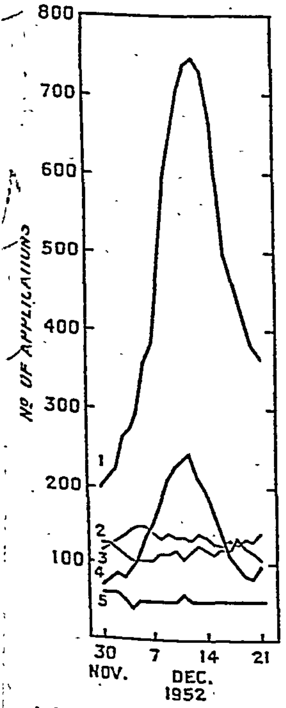
—Percentage of patients admitted to hospital in November and December, 1952, (a) daily and (b) by moving weekly totals.

ications rose very rapidly, reaching an unprecedented : on Dec. 9, when 492 were received. Applications inued in abnormally high but diminishing numbers l the 13th, after which a fairly stable state was hed (fig. 1).

a Dec. 1 the admission-rate was 88·5%, and in spite ncreasing pressure it was kept above 85% until lay, the 7th, when it fell to 84·9%; a "white" ning was issued at 11 A.M. next day (fig. 3). On sday, the 9th, the rate was 79·9%, and the "yellow" ning was issued. The response was such that, despite high total of applications, the admission-rate fell a further 1·5%. The "yellow" warning was cancelled on the 15th, and the "white" on the 17th.

Prior to these warnings the admission-rate had been maintained above 85% by the action of the regional medical admission officers, who freely used the power to refer any given case to the group medical referee for immediate admission. This must have been a very severe burden on the regional-board hospitals.

It is interesting to note that, whereas on Jan. 1, 1951, at the height of the influenza epidemic, 293 applications were received by the E.B.S. and 185 cases were admitted, on Dec. 9, 1952, at the height of the fog "plague," 492 applications were received and 390 cases were admitted. The highest weekly total of admissions previously recorded was 1169 on Jan. 2, 1951; but in the week ended Dec. 13, 1952, 2019 cases were admitted.



: 4—Weekly totals of applications n December, 1952, by types of lisease. (1) Respiratory disorders. (4) Cardiac disorders. (3) Other acute medical disorders. (2) Acute surgical disorders. (5) Cerebral hæmorrhage.

TYPE OF ILLNESS

The increase in sickness was due almost ntirely to respiratory disease, which was nearly quadrupled (fig. 4). The rise in heart-disease to about three mes the normal numbers, though less spectacular, should ot be overlooked. As in the winter of 1951–52,[1] the increase in sickness was almost exclusively confined to the over-45 and under-5 age-groups.

CONCLUSION

The warning system appears to be satisfactory, and the magnificent response by the hospitals undoubtedly saved the day.

EFFECTS OF A SEVERE FOG ON A GENERAL PRACTICE

JOHN FRY
M.B. Lond., F.R.C.S.
GENERAL PRACTITIONER, BECKENHAM, KENT

THIS is a report on the effects of a severe fog on a general practice of 4500 patients in the south-eastern outskirts of London. The fog reduced visibility at times to nil, and persisted for five days from Dec. 5 to 9, 1952. It was preceded and accompanied by intense cold; illness was widespread, and there was an increase in the number of deaths. In the week ending Dec. 13 there were 4703 deaths in Greater London, compared with 1852 in the corresponding week of 1951; and during the same week the Emergency Bed Service dealt with 2007 hospital admissions, compared with 917 in 1951.

VOLUME OF WORK

There was a remarkable increase in the work of the practice during the period of the fog and the following two weeks. This was largely accounted for by the increased number of visits that were necessary. The normal average number of weekly visits for this time of year is 75; during the week of the fog the number rose to 125. The number of attendances in the surgery did not vary from the anticipated average, which is 250 consultations per week.

TYPE OF WORK

There was a considerable increase in the prevalence of two conditions—namely, the upper respiratory tract affections and the respiratory disorders. The former included all coughs and colds with no abnormal chest signs and with relatively little constitutional upset; "respiratory disorders" means all conditions with symptoms referrable to the lungs and where abnormal signs were detected.

Table I shows clearly this rise during the period of the fog compared with the number of attendances for the preceding three weeks. Of course, these figures give no idea of the total number of people affected by the fog, for very many did not seek medical advice.

Upper Respiratory Tract Affections

Between Dec. 1 and 22 201 people sought medical advice for symptoms referrable to the upper respiratory tract. The chief complaint was a very irritating cough, with little sputum; what sputum there was was black or grey mucoid material. Nasal discharge and sore throat were the other prominent symptoms. All ages were affected, but there was a high proportion of patients in the 40–50 age-group. No abnormal signs were detected in the chests of these patients.

TABLE I—ATTENDANCES FOR UPPER RESPIRATORY TRACT AFFECTIONS AND FOR RESPIRATORY DISORDERS

Week	Nov. 10–16	Nov. 17–23	Nov. 24–30	Dec. 1–7	Dec. 8–14	Dec. 15–21
No. of attendances for upper respiratory tract affections ..	36	48	47	68	94	75
No. of attendances for respiratory disorders	19	29	30	51	93	62

1. See Abercrombie, G. F. *Lancet*, 1951, ii, 1175.

welfare service for children provided in temporary premises such as church halls Fortunately this decision has, I understand, been reversed

The extracts in last week's issue from the report by the medical officer of health for Glasgow is a welcome warning, indeed Dr George and his colleagues stress the need to maintain the welfare centre distinct from the doctor's surgery

Dr Tabbush in his stimulating letter last week misses a very important point—the time factor With many general practitioners it is the lack of time which makes it impossible for them to give satisfactory preventive and supervisory medical care Linked with the higher capitation fee which he suggests for children under 5 there should be a reduction in the list of the doctor wishing to work in clinics, this would then give the general practitioner the right to work in a local-authority clinic if he wished The same principle could be applied to those wishing to undertake obstetrics

By the courtesy of the medical officer of health I have at present the opportunity of seeing some of my antenatal patients at the local welfare centre with the midwife present and the health visitor available if required, and I find this a great advantage I should welcome the same opportunity to work in a child-welfare clinic, but would have great difficulty in finding time unless I curtailed my general-practice work

Let us hope that the useful analysis, by Dr George and his colleagues, of child-welfare clinic work will be followed by a similar analysis of the work of the school medical clinics

Many of the problems we are attempting to solve today without health centres will be more easily dealt with when we have them, meanwhile let us ensure that the concrete buildings of the local authority clinics are not swept away, whatever sweeping changes may take place within their walls

Birmingham M BARROW

AUGMENTED RESPIRATION

SIR,—There are two points in the article by Dr Donald and Dr Lord (Jan 3) on which I would like to take issue with them

In the first place the persistent failure of less ingenious methods raises doubts as to whether artificial respiration, however effected, can modify the physical state of the atelectatic lung in the newborn, beyond just overdistending the alveolar ducts [1] [2] Some hold that the cause of the atelectasis in many cases is alveolar cohesion from delayed absorption and progressive desiccation of normally aspired amniotic fluid, and if this supposition is correct the value of enforced respiration in increasing oxygenation might be offset by its action in accelerating this process The view of Dr Donald and Dr Lord that the atelectasis at autopsy in their cases is unrelated to the antemortem state cannot be accepted, for in similar cases there is often persistent aeration of the upper and right middle lobes after death

Secondly I would question that clinical spirometry, as described, is of value as a diagnostic aid The authors do not state how they calibrated their apparatus or what the margin of error was with varying speeds and tidal volumes with and without leaks Furthermore in my own experience the range of minute volume in newborn infants, both normal and with respiratory distress, is so considerable, especially if crying periods are included, that it is valueless to accept and compare readings unless they have been obtained under well standardised basal conditions

DONOUGH O'BRIEN

HOSPITAL COSTS

SIR,—Consideration is now being given to the proposals of the Nuffield Trust and the King's The general idea seems to be that comparison mental costs in different hospitals may lead to and, as regards money, this may be true

But I believe that comparison must be betw things which are generally equal and differ only or two significant factors In the kind of (mental deficiency) in which I am interested, any functional units, whether departments or ward differ in as many as seven important aspects wh directly affect cost True conclusions are unlik such variable conditions

A particular fallacy is the assumption that is equal in the two units under comparison The of a unit, or the happiness of the patients or or the progress of the patients, or the satisfactio to their relatives, cannot be measured, and the unit is not necessarily as good as the more exp any of these respects The opposite is also tr more expensive is not necessarily better than the

These imponderables cannot be given money and, from the medical and nursing point of view cannot be the only criterion of economy in essentially a human activity Doctors must alw apprehensive lest the proposed costing system lead imposition of false standards in the care and tr of patients

The report of the King's Fund shows some aw of this point of view but does not really m difficulty

CONSULTATION AND CONTROL

THE MINISTRY'S ASSURANCES

Jan. 6 the members of the Joint Consultants Com- ee met Sir John Hawton and other officers of the stry of Health.

r Russell Brain, chairman of the committee, said the profession was extremely disturbed by recent its which seemed to point to an unwillingness on the of the Ministry to consult the Joint Committee or to keep it informed on matters in which it was lly interested, and on which its advice would be of greatest help to the Ministry. There also appeared e a growing belief on the part of the Ministry that the pital and consultant services should, and could, be rolled in detail from the centre.

eferring to the recent circular letter to boards of ernors of teaching hospitals, concerning medical blishments, Sir Russell reminded the Ministry that undertaking had been given that the results of the ical staffing survey undertaken by inspecting teams ld be discussed with the Joint Committee in general as before any decisions were taken. Although the ter was one which profoundly affected consultants, undertaking had not been fulfilled. On the contrary communication to boards of governors had been owed—again without the knowledge of the Joint mittee—by the recent circular to hospital boards and [illegible]: a 5% reduction in certain categories [illegible], [illegible]ezing the establishment of medical f and prohibiting any expansion except with the sent of the Minister. While medical staffs were luded from the 5% reduction, an examination of the ommendations of the inspecting teams revealed that ut into effect they would achieve almost exactly a reduction in the consultant establishment of teaching pitals. If the inspecting teams' recommendations olved a similar reduction in the case of regional rd hospitals it would mean the termination of the tracts of some 300 part-time consultants. It was e that the matter had not gone beyond the stage of ommendations; nevertheless it was difficult to avoid assumption that the recommendations indicated the nistry's intentions. Moreover, the Ministry's instruc- ns on economy in staffing made no distinction between spitals which were economically planned and those ich were not, and Sir Russell wondered what could be re discouraging to a conscientious hospital authority. e Ministry's attention was also drawn to the damaging ect of the recent instructions on the problem of sorbing the surplus of senior registrars.

Sir Russell Brain pointed out that further evidence of reased centralisation was to be found in the recent structions for statistical recording of the work of thological and radiodiagnostic departments. The easures suggested were open to serious criticism, and ere was a very real danger of over-standardisation. part from the fact that these instructions involved an borate recording system which would require addi- onal clerical assistance, they implied a belief that the ork of these departments could be assessed in terms of atistics and ignored the human element of its value the community.

He reminded the Ministry that the Joint Committee ad repeatedly urged the need for consultation with the rofession at all levels in the service. The committee, ad consultants generally, were very willing to help the inistry, but could not do so unless they felt that they ad the Ministry's confidence. Unfortunately, on a umber of occasions the committee had been placed in n invidious position. It had either had to explain to the profession that it had no prior knowledge of the Ministry's intentions in a particular matter, or to remain silent and appear to consent to something it felt it should criticise.

In reply, Sir John Hawton said that, although he readily admitted that there had been occasional failures on the part of the Ministry to consult the Joint Committee, these were lapses in performance rather than in intention. The Ministry from the outset of the service had always been anxious to consult with all the bodies concerned with hospital policy. They had no wish to depart from this position.

Dealing with the communication to boards of governors on medical staffing, Sir John agreed that it would have been better if the Joint Committee had been consulted, but the failure to do so was an error, and not an intentional one. He wished however to correct any mistaken impressions on the matter. The proposals that had been sent to the teaching hospitals were simply those of the inspecting teams. They were not the conclusions reached by the Ministry itself, nor was there any intention on the part of the Ministry to impose them on the boards. It was open to each hospital, and particularly to its medical staff committee, to look freely at them and interpret them in the light of their local knowledge. The Ministry was only too anxious to have the views of the hospitals themselves.

Referring to Sir Russell Brain's comment on a possible reduction of medical staff arising out of the staffing survey, Sir John said that similarity with the 5% reduction called for in the other grades of hospital staff was purely coincidental. There was no intention of imposing a 5% cut on medical staffs, and the Ministry had at the moment reached no conclusions.

Regarding other lapses in consultation, he hoped that the committee would appreciate that on occasion it was necessary for the department to announce an important item of Government policy without prior consultation with the profession, but fortunately this would be a rare occurrence and did not affect the general position. He added that there was no desire for increasing centralisation, and if centralisation had increased since the service began it was due not to any desire for it for its own sake but to the need for an over-all control of hospital expenditure, for which the Minister was responsible to Parliament.

Sir John Hawton stated that the Ministry was in full agreement with the Joint Committee on the need for effective consultation. He did not think this need could be formalised; it was rather a matter of the two sides keeping in close touch with one another. He gave an assurance that the Ministry, for its part, would do all in its power to provide effective consultation with the Joint Committee on all matters affecting consultants in the hospital service. The Joint Committee need be in no doubt as to the Ministry's recognition of the committee as the body speaking for consultants and members of hospital staffs, and of its very real desire to coöperate with the Ministry for the good of the service.

COLLEGE OF GENERAL PRACTITIONERS

The new college has issued a statement on some aspects of its work, inviting suggestions and help from practitioners.

Teaching of General Practice.—One of the objects of the college is to assist in the training of final-year students (and those newly qualified) in the principles and technique of general practice. It is already in touch with many medical schools that have started schemes by which young men and women get their first introduction to general practice by attending the surgeries, rounds, or lectures of general practitioners of experience; and information is being collected about these methods.

committee was able to advise the industry as to which *oils were relatively safe and which were unsafe*

The Local Government Act of 1929 gave further scope to Dr Veitch Clark's administrative ability This Act transferred to the city the functions of the former board of guardians In consequence, the public-health service was expanded to include a general hospital and pathological service, district medical and public vaccination services, and the work of infant life protection Dr Veitch Clark tackled vigorously the reorganisation of the former poor-law infirmaries, which speedily became active and first-class general hospitals The number of beds under his care rose from 1000 to 8000, and he gladly accepted the consequent administrative responsibility for a proper visiting consultant service, and for recording hospital statistics The Act also required the local authority to consult with representatives of the voluntary hospitals to avoid wastage of beds in municipal hospitals and shortage in others The success of the consultations led Dr Veitch Clark to propose that a permanent body should be set up, and in 1935 the Joint Hospitals Advisory Board was formed

He also welcomed the passing of the Housing Act, 1930, and his slum-clearance campaign, which removed from the city several bad areas of slum houses, was only interrupted by the outbreak of war in 1939 He was a man of strong character, and by example he inspired his staff to keenness and efficiency His readiness at all times to help and encourage his junior colleagues won their respect and affection

He served as president of the Society of Medical Officers of Health for the year 1934–35 and he was appointed honorary physician to the King in 1941 The following year he retired from his official duties, but only to continue to work as a senior hospital officer of the Ministry of Health Later he settled in the border country and made his home at Peebles

His wife died some years ago, but he is survived by a son and a daughter

THOMAS SHIRLEY HELE

O B E, M A, M D Camb, F R C P, D P H

Dr Hele, a former vice-chancellor of the University of Cambridge and master of Emmanuel College, died on Jan 23 at the age of 71

He was born at Carlisle and educated at Carlisle Grammar School and Sedbergh Though he came of Devon stock he appreciated the kindly severity of his northern upbringing, and he often recalled with affection and respect the rigours of his schooldays In 1899 he went up to Emmanuel College, Cambridge, where he took firsts in both parts of the natural sciences tripos, and in 1903 he took his London B SC with honours in physiology Meanwhile, with a Shuter scholarship, he had entered St Bartholomew's Hospital, where he qualified in 1906, taking his M B Camb the following year With a B M A research studentship he worked with Archibald Garrod on diseases of metabolism, and in 1909 he published a paper on cystinuria in the *Journal of Physiology* While still undecided whether to choose a career in clinical medicine or in research he took the D P H, and he also held house-appointments at Barts and at the Royal Infirmary Bristol Thus when in 1911, his college offered him a fellowship and he finally decided to choose research he approached his work in the laboratory with a wide experience of bedside and preventive medicine

His work at Cambridge was interrupted by the 1914-18 war when he served with the R A M C in Salonika Here his public-health experience proved valuable, and he used to describe his war-time post as that of professor of nuisances In 1919 he returned to his more formal academic activities at Cambridge, and in 1921 he was appointed university lecturer in biochemistry and in 1922 tutor of his college The burden of these administrative posts deflected him from research work he had begun with Gowland Hopkins Later he added to them the secretaryship of the faculty board of medicine and membership of the General Medical Council In 1935 he was appointed master of his college, and from 1943 to 1945 he served as vice-chancellor of the university In 1940 he was elected F R C P

Although Dr Hele filled high academic offices for many years he was no lover of formal occasions He could bear with a modicum of traditional cer
but he was sensitive to the slightest suggestion of
Not the least valuable quality he brought to

MONTAGUE HENRY KNAPP

M R C S

Surgeon Captain Knapp, who died on Oct 13,
age of 84, played a big part in obtaining recog
and employment as trained male nurses for men of
sick-berth branch on their retirement from the
Navy after twelve or twenty years' service It
largely due to his efforts that the Nursing Act
reopened the list—closed in 1925—to Naval p
then qualified to register as State-registered nurs
Act also provided that sick-berth ratings with
qualifications were to be recognised as "Service-
male nurses," and could call themselves "nurse
practise as such, although not registered as S R

The son of Lieut Colonel Charles B Knapp, he recei
medical education at Queen's College, Cork, and St
Hospital, London, where he qualified in 1892 Two year
he joined the Royal Naval Medical Service Before he
in 1921 he had held such varied appointments as
officer in the training ships *Lion* and *St Vincent*, and
medical officer at the R N. Hospital School at Greenw
a plague camp at Bombay, and at Admiralty recruiting
quarters *He held the Order of Liakat of Turkey* and
knight of the Order of St John After his retirem
honorary appointments included the directorship of
Naval medicine section of the Imperial War Museum, the
manship of the Lord Chancellor's Pensions Appeal Tri
and the vice presidency of the Medico Legal Society
his main interest, of course, remained the R N Sick
Staffs Associations, and for many years he was the
chairman of the executive committee of the central
of the associations

J F H writes "It was Surgeon Captain Knapp's
tention that men of the sick berth staff who by tra
service, experience, and examination had attained the ra
sick berth petty officer should automatically qualify
admission to the State Register of Nurses He long reg
having been unable to ensure this deserved right for
officers of the sick berth branch, and he felt strongly
the want of timeous senior official support, and the agree
with the other Services and acceptance of the lower level
'Service trained male nurse' for fully and partly tra
Naval nursing personnel alike But many who served d
the late war, and became recognised as 'Service trained
nurses,' were with this status enabled to attain Regi
status the long way For most of us that might seem ach
ment enough in the higher octave of life, but it never sat
Surgeon Captain Knapp"

Births, Marriages, and Deaths

BIRTHS

CRAIG—On Jan 23, at the Bristol Maternity Hospital to
Jean Craig (née Simpson), wife of Dr R A Craig—a son.

HEATHFIELD—On Jan 13, at Chigwell, to Dorothy, wife of
K W G Heathfield, M R.C.P—a daughter (Angela)

PORRITT—On Jan 19 at 31, Queen's Gate, London, to Kay,
of Sir Arthur Porritt, K C M G—a son

MARRIAGES

LOVIBOND—CAREW JONES—On Dec 12, in London John L
Lovibond T D M D M R.C P, to Mary Carew Jones

rouses in us secret sympathies; for here is the ade, the lame god, our shadow self, the dark and knowledged side of brindled human nature. Here od so close to us that even the shallowest modern still ; his bold licentious whispers, yet so remote in origin without experience of him Man would not be Man.

der than all these are the dim unfocusable forms that ng "like pageantry of mist on an autumnal stream" nd the enigmatic figure of young *Jimpy*. These dim es are indeed the early gods, older far than "the ht static hierarchy of Olympus," older perhaps than e itself. They reach back, these primal figures, to e fluid ever-changing changeless archetypes that m and glow in the depths of the archaic psyche. edibly, *Daily Mirror* Jimpy is of their company. nally childlike, vague of parentage, he displays startling fidelity the weakness and insignificance bined with mysterious power possessed by the dawn- ge of god in the human mind. At one point in the e an adult character says to him, "Is it true, then, must always remain a boy?" It would be hard to se a clearer modern evocation of the Puer Æternus. ss, indeed, Barrie's sentimental and emasculate ion is adduced.

erhaps the key to the whole mystery of the comic 's compulsive force lies in this Jimpian paradox of kness and smallness combined with magical, boundless er. For paradox itself, that disquieting insult to ived opinion, is usually a pointer to the heart of gs. The approaches to wisdom are paved with kly paradox; hard going for bare rational feet.

Smaller than small, yet bigger than big." In these arently senseless words are expressed the earliest epts of the divine in the history of the human mind: Little Copper Man, for instance, of the Finnish *evala*, "no bigger than a thumb and no higher than x-hoof," who yet could fell the giant oak tree that ered the sun and moon with its branches; or *ayana*, the little Hindu boy asleep in the nyagrodha , in whose belly lay "the whole world with its lands cities, with the Ganges and the other rivers and the ." In widely differing cultures the same paradoxical kness-and-strength is visualised: in David with sling, Hercules strangling serpents in his cradle, Eros ed with fatal arrows, and—little Jimpy, deferential dults but gifted with his magic powers.

THE RETURN OF THE GODS

here is, of course, something both offensive and rageous in these parallels of the sublime with the enerate-ridiculous. The association is lunatic and the ional mind recoils from it at first in repulsion and gust. The rational mind should calm itself. There ve been in myth and legend many such divine *boule- sements*: as of Jove, lord of an antique heaven, indling down to bottle-nosed Father Christmas among kitchen pots and pans—though later, it is true, omoted to reindeers and a fur coat. That these cheap d paltry images in the corner of a popular newspaper ould have spiritual significance is painful to contem- ate. And yet, if accepted, it emerges as but one more istration of a phenomenon to which, perhaps the iverse is subject: *enantiodromia*, the incessant inevit- le turning of all things into their opposites. Heraclitus, Jung points out, was first of European minds to press this concept philosophically, but its parentage far more ancient. The *tegitu*, Chinese symbol of guessed age, conveys the same concept with incom- rable wholeness and precision. A white fish with a seed blackness at its centre curves into a black fish with a ed of whiteness, to form a perfect circle; each fish anges eternally into its opposite. What was important rried within itself the seed of its own destruction, and slowly emptied of meaning; what was derided carried orgotten truth, and leads to a new valuation.

Seen by this light, the values we now neglect, the stone which the builders have rejected, should be looked for in some such unexpected corner of daily life. It is a measure of our neglect that these values are forced to put on so mean a mask in order to re-enter human consciousness. The comic strip by its pathos and infantilism, by the derision it arouses, by its astonishing universality of appeal and crude vitality, fulfills the historic conditions for "the return of the repressed." The comic strip is in fact a ludicrous but valid symptom of our disease. For in one form and another "the return of the repressed" is precisely what is making the present century rock and quiver with premonitions of eruption.

Unpalatable though it may be to modern taste, the truth is that we cannot live without the early gods. It was said of Nature that even if you throw her out with a pitchfork she nevertheless comes back. So do the gods. If cast out in the forms of Man's profoundest apprehensions of them—if Christ and Buddha and Mithra, if Ashtaroth and Pan, are disowned—they nevertheless come back. However meanly and unrecognisably, they come back to the human heart whose inevictable tenants they are. And "there all smothered up in shade" they sit, radiating that strange compelling power which is Man's unconscious tribute to the Unknowable. In the comic strip may lie concealed the indestructible germ of natural religion.

Parliament

Grants to Marriage Guidance Organisations

In the House of Lords on Jan. 21, Lord MERTHYR, chairman of the National Marriage Guidance Council, deplored the drastic reduction in Treasury assistance to these organisations. The figures for divorce had now settled down from the peak reached in 1947 to a steady 30,000 a year, which was four times the figure for 1939. He believed that for every divorce case there was on the average a little more than one child involved. And this took no account of unhappy marriages which did not result in divorce. In his view delinquency could be unerringly traced back to broken homes and unhappy marriages. To say that it might prove cheaper to tackle delinquency early might be a platitude, but it was none the less true.

Marriage guidance, he continued, was a new thing, and the Treasury grants had been largely spent on the training of marriage guidance counsellors who gave their services without pay. A year ago these grants were suddenly cut by half and this had dislocated the work. Lord Merthyr estimated that under the scheme for legal aid some £1,200,000 a year was spent on matrimonial cases, yet grants for marriage guidance had been cut from £12,000 to £6000 a year. So we are spending two hundred times as much helping people to get divorce as on trying to guide them away from it.

Lord LLOYD, who replied to the debate, said though marriages were made in Heaven they had to be lived on earth Housing difficulties today led to many broken marriages. But even so we must ask ourselves whether the institution of marriage was still anchored by an effective public opinion. If it was not, how was that effective public opinion to be built up again? We would deceive ourselves if we imagined that this terrible problem could be overcome merely by an expansion of marriage guidance councils; something more was needed. But he agreed that the Government, and everyone else, should do everything possible to arrest this lamentable trend.

On the face of it, he admitted, it was unfortunate that as a nation we should spend so much money helping people to break up their marriages, and so little trying to stop them getting divorced. But if the principle of legal aid was accepted we could not say "you may have aid for this kind of case, but not for that." He hoped that in time the amount spent on matrimonial cases would be reduced. The present spate of divorce, he believed, was largely due to an accumulation of marriages which were already broken but which had not been order to meet them Dr Palmer evidently feels that psychiatrists are shaky in their grasp of symbols and meaning, for he proposes that they should receive a training in philosophy, "so that the intended meaning of terms used by them shall be stipulated, and the esotericism and the ambiguities of syntax so characteristic of their specialty shall be reduced to a *minimum* Only by so doing can the discussions of psychiatrists become communicable and discussable" While many will approve his aim, not all will agree that a course in philosophy is the only—or indeed the best—way of learning to use language without ambiguity

FILM OF THE BLOOD-FLUKE

IN the *Human Blood fluke* the staff of the Wellcome Research Institution has produced a colour film of the first quality This is in two sections the first deals with the life history of the human schistosomes in general, and the second with methods used in chemotherapy The film, which runs for about 40 minutes, has the advantage of having been taken by a great expert in colour photography and also of being provided with a sound track from which emanates an admirably clear, concise, and intelligible running commentary This demonstrates clearly how well suited a film of this nature is to students and research-workers alike Brigadier J S K Boyd, F R S, who introduced the film when it was shown in London on Jan 22, paid tribute to O D Standen, the director, Miss Florence Anthony, the producer, and Douglas Fisher, the photographer

The scheme which this film illustrates was commenced six years ago in an endeavour to infect water snails in the laboratory with blood flukes and eventually to produce active therapeutic agents and efficient molluscacides This entailed devising many novel techniques, both in rearing and maintaining colonies of freshwater snails in the laboratory, and in infecting laboratory animals with the schistosomes The film ranges over every aspect of this subject The species of schistosome selected was *Schistosoma mansoni*, which can readily be maintained in white mice, though golden hamsters and macaque monkeys are also very susceptible A survey made of the two other species of human schistosomes is also given, and there are pictures of their eggs and their snail hosts, as well as maps of their respective geographical distributions, from which it appears that about a hundred million people in the world are infected with schistosomes of one kind or another There are scenes showing absence of sanitation and the background of schistosomiasis in the Nile Valley, and the propaganda methods which have been devised to combat it The life history of the parasite in the human body is illustrated by actual photographs and by diagrams Egg deposition in the mesenteric veins by the female fluke, and the by passing of some ova which are then swept back past her head to be deposited in the liver, are excellently shown There are pictures of the live adult schistosomes moving up and down the blood vessels Then comes the deposition of the egg and the hatching of the miracidia, which dart around like some miniature meteors, and, more miraculous still, the miracidial bombardment of the antennæ of the snail which frantically attempts, by waving them about, to ward off their ferocious onslaughts, and finally development within the snail's liver (shown diagrammatically) and the clandestine and dramatic escape of the cercariæ in showering shoals from the snail host into the surrounding water Their free life lasts only 48 hours, but the pictures show that they make the most of it Next there is the dramatic penetration of the cercariæ through the skin and the shedding, in most instances, of the tail, invasion of lymphatic vessels, and ultimate arrival in the left subclavian vein and right side of the heart The journey is once more traced to the portal vein, where the schistosomulæ become mature and recommence the cycle Fæces of infected white mice produce the best crop of miracidia when subjected to special concentration techniques which have been elaborated The snails are infected in special glass jars, allotting 15 miracidia to each mollusc *Australorbis glabratus* the South American species, is the most susceptible snail and thrives best in self contained and balanced aquaria They flourish on a specially compounded food which is made of gel, eggshells, milk powder, 'Bemax,' and calcium algenate Some 150 cercariæ are applied to each mouse, and the adult worms become mature in 50 days

The chemotherapy section is most instructive and illustrates a new squash technique by which adult flukes may be demonstrated and studied in the liver itself This is most important since it has been shown, with inadequate therapy by 'Nilodin' or the antimonials, that many flukes escape unscathed into the liver If not sufficiently damaged by the drug they soon recover there, illustrating the mechanism of relapse By these means it has been shown that the antimonial drugs are three times more active than nilodin The first specific effect of an antischistosome drug is seen on the female worm, which immediately relaxes her hold on the vessel wall and is swept back into the blood stream while her more robust mate hangs on for some time longer before going to his grave

Small wonder that enthusiasms are raised in parasitologists and clinicians alike by a beautiful practical demonstration such as this

FOOD AND THE CARDIOVASCULAR SYSTEM

THE American Heart Association includes among its many useful publications a booklet on diets,[1] which first sets out some principles for patients with heart disease or hypertension, and then gets down to business, describing in detail (and with recipes) diets for reducing, and low sodium diets An appendix gives the sodium content of common foods (including public water supplies) The principles are well set out, and of course apply universally, but the diets, unfortunately refer to American rather than British tables Still heartening for those who are overweight to find th ordinary intake might very well qualify, in Americ reducing diet for not everybody expects to get much more in a day than a pint of milk, 5–7 oz 3 or more servings of vegetables, three slices of bread, teaspoonfuls of butter, and four servings of fruit

But if we may be better placed than Americans for reducing we encounter far more obstacles than they do when attempting a diet severely restricted in sodium For them, such things as low sodium breads, salt free canned and frozen vegetables unsalted butter and cooking fats, and low sodium milk are to be had, it seems, for the asking The British hypertensive pursuing such rare game would probably starve before he had bagged his first breakfast Nevertheless, this is a highly informative booklet, full of facts and hints, most of which can be interpreted to apply in a general way to British feeding customs, and it is designed for the use of doctors as well as patients

MORE X-RAY FILM

Messrs Ilford Ltd announce the completion of new plants for the coating of X ray film and the manufacture of film base They say that the output of these plants will end the shortage of X-ray film in this country All X ray film base has hitherto been imported, largely from the United States, and its manufacture in large quantities at home will mean a considerable saving of dollars The film base is being made in a plant owned jointly by Ilford Ltd and BX Plastics Ltd

AN ITALIAN TOUR

AT the end of May last year 130 members of the International Hospital Federation visited hospitals and other medical institutions in the region of Milan, Bologna, Rome, and Genoa A report of this study tour has now been published, and copies may be had from Captain J E Stone, the secretary of the federation, 10, Old Jewry, London E C 2

University of Cambridge

The Nuffield Foundation has made a grant to the university of £8650 spread over five years, in support of work in experimental embryology under the direction of Prof J D Boy in the department of anatomy

University of Birmingham

On Dec 19 the following degrees were conferred

Ch M—M J Roper Hall

In England Now

unning Commentary by Peripatetic Correspondents

IOSE who question the value of notifying infectious se have never squatted in general practice. To e of us who have, the half a crown for each notifica- represents a good return on 1½d. postage. There of course, a few finer points worth noticing. not make the common mistake of forgetting pneu- ia, which is surprisingly common if you only look it. And what about whooping-cough? It is notori- y difficult to diagnose, so who can blame you if you ake an ordinary catarrhal infection for it? Then, n, I found that I was seeing many cases of d. and v., ch I presumed were due to food-poisoning (notifiable). s I am now satisfied was an error, as the sanitary ector pointed out. He said that the M.O.H., worried the rising incidence of food-poisoning, was insisting each case be investigated and specimens sent to the The S.I. suggested, rather diffidently, that these s were really due to Sonne dysentery. I agreed him that they were certainly cases of dysentery ifiable). The M.O.H. is satisfied that his prompt on put an end to a disturbing increase in food- oning.

carlet fever has been a big disappointment. Taking rôle as a health educator seriously, I always pointed to the parents that the diagnosis had no serious ificance, the illness being only an ordinary sore at with spots. This proved difficult to reconcile the appearance at the house of a fumigating van harge of the sanitary inspector, who proceeded to up the sickroom and to carry on in a most alarming ner. In a phone conversation, the health depart- it agreed with my view that this procedure was eless, but I was assured that, as his field of activity now so restricted, the M.O.H. insisted on it being tinued until the Minister says it is to stop. Since n, unfortunately, I have had no cases of scarlet er, but only sore throats with spots.

* * *

One of our colleagues on rare occasions travels to ndon to attend meetings, when he usually has a blame- s and uneventful midday meal at B.M.A. House. Last ek, however, he took his wife with him, and, one ng leading insensibly to another, he found himself ring lunch in one of these Temples of Fashion which est the broader streets of the Metropolis. He was half y through his chicken-and-ham patties (our colleague not a clinician, and cannot afford to aim high), when observed that his wife's eyes had narrowed, and, ning lethargically round, his gaze encountered that an exotic raven-haired beauty, liberally besparkled, d in full off-the-shoulder evening dress. The beauty ecuted a couple of brisk pirouettes, and, taking the unce of her skirt in one hand, swished it smartly at r colleague. After which she smiled radiantly and thdrew, leaving a large central scotoma in our col- gue's visual fields. Nothing in his previous experiences B.M.A. House had prepared him for such a pheno- enon, and he spent the rest of the meal in an uneasy ate. At intervals he fancied he heard a rustle of taffeta hind him and whipped round at great danger to life d limb only to find the waitress regarding him stolidly. uring his steamed fruit pudding he several times felt e hot breath of further exotic beauties on the back of s neck, but investigation disclosed no basis for this nsation, and he left the restaurant without any ditional manifestations being vouchsafed.

Nevertheless, the experience has left its mark upon m, and even while sitting in our own canteen he has a ndency to twitch violently and scrutinise the space mediately behind him. He expresses himself as issatisfied with rural life.

* * *

My practitioner friend, fuming after an altercation with patient who did not carry out his instructions, declares at things are not as they used to be. Wistfully recalling e good old days when patients were patients, he related ow, soon after he took over his present practice, he was alled to attend a lady with a fibrositis. For this he successfully, or fortunately, prescribed. On his next visit he said that she could now leave her bed. After a shocked silence he was coldly told that the patient had been bedridden for several years. Swallowing his pride my friend re-examined her but was unable to find a cause for such a grave drawback. Finally he elicited the following history:

> Seven years previously she had had severe chest pain with a high fever. My friend's predecessor had diagnosed a "congestion of the lungs." The patient, a hard-working housewife with a large family, had refused to go to bed. The doctor without further ado called the husband and eldest daughter. He told them that the patient was seriously ill. She must go to bed and stay there until he returned. On her feet she might collapse and die, and if she arose prematurely the results might be grave. Unfortunately he forgot to return.

With difficulty my friend persuaded the family that the patient could now safely rise, and later that she could even get out. On her first walk she found a housing scheme had been built in the green fields in front of her house.

* * *

Thoughts on the Archers: a problem family—always in some trouble or other—masochistically provoked, no doubt.

Dan Archer—constant undercurrent of pessimism barely concealed by forced conviviality—E.C.T. for him. Mrs. P.—flat monotonous voice—obviously Parkinsonian—try a dash of belladonna. Phil Archer—dithering about from one girl to another—Don Juan complex—analysis the only hope—he'll never save £2000 with that outlay—still, can't be helped. Better send Grace Fairbrother along too—must be lots of unhealthy fantasy there, the way she carried on when her stepmother became pregnant. Walter Gabriel—obvious inadequate psychopath—brisk course of rehabilitation at a neurosis centre followed by fortnightly supportive O.P. interviews—threaten leucotomy if he turns awkward. Spot of 'Antabuse' for Reggie Trentham. Marriage Guidance Council for Jack and Peggy. A good P.S.W. for Mary Jones. A bucket of 'Benzedrine' for the rest.

Let's see now—nine consultations at 5 guineas a go—45 guineas—bill to the Director-General at the end of the month—that should pay for my wireless licence for a few years to come.

* * *

An interesting point in diagnostic parasitology was raised on a recent visit to the farm. I had been scratching the biggest sow's ear for some time before I noticed the reason for her obvious enjoyment, and withdrew my hand quickly. My youngest brother noticed me abstractedly scratching my wrist some time later and asked if I were being bitten. We had a look, and a minute form of life went scurrying down the back of my hand from where it had been cowering under my wrist-watch. "A louse or tick or something," I said with the vagueness of a medical practitioner in the presence of his family. "That was a tick," said my youngest brother with assurance, and waited just the right length of time before adding "it came out of your watch."

* * *

THE REWARD OF VIRTUE

How patiently I strove to gain
Your confidence, but all in vain,
You peevish little pest.
How thoroughly (although you fought)
Examined, as I knew I ought,
Your little wriggling chest.

How reassuringly addressed
Your anxious parents, little pest,
And curbed their foolish fears;
Resisted the desire to smack,
Patted your father on the back,
And dried your mother's tears.

And having done my level best
For you and yours, you little pest,
I edged towards the door,
Only to hear your mother say;
"The nasty man is going away,
So don't cry any more."

Diary of the Week

FEB 1 TO 7

Monday, 2nd

INSTITUTE OF PSYCHIATRY, Maudsley Hospital, Denmark Hill S E 5
8 P M Prof Konrad Lorenz (Buldern, Westphalia) Comparative Psychology and Psychiatry

Tuesday, 3rd

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields W C 2
5 P M Dr A A G Lewis Control of the Excretion of Water by the Human Kidney (Arris and Gale lecture)

BRITISH POSTGRADUATE MEDICAL FEDERATION
5 30 P M (London School of Hygiene and Tropical Medicine Keppel Street, W C 1) Prof E J King PH D Silicosis and Asbestosis

Dr GEORGE DUNCAN has not accepted the post of asst M O H for Burton upon Trent (*Lancet*, Jan 17, 1953 p 152) ost of the "underdeveloped" countries, the child h services are rudimentary, and in many places are ineffective because they have developed on established patterns—patterns unsuited to local needs and itions.

ke for example the maternity services. There has much concentration on building maternity hospitals on training midwives. Yet the antenatal work is slight and perfunctory and the postnatal work existent. But the main causes of maternal and infant ology are malnutrition, overwork, anæmia, and ated pregnancies in the mother. It is quite impossible any of these conditions to be affected simply by iding expert assistance at parturition.

hild health services should be established only after observation of the needs and resources of the le. They should then be built up in close coöperation the hospitals and in such a way as to make the test possible use of any available personnel.

small proportion of the money now being spent on tific work should be devoted to social observation experiment. I am convinced that it would not be before the revolutions in motherhood and in agriure that you mention could be within our vision—copic vision though it may be.

his is not idle fancy. I have seen the beginning of k in various countries that has actually changed the of the people towards better nutrition and living litions. But such experiments have been starved for ls and for personnel. They have never been provided the possibilities of development and expansion, of tinuity, and of publicity that would have established r value.

these days when the terrors of over-population are oming a real menace, surely we can persuade some of authorities to use the only really possible and effective ence—adequate care of the children automatically lts in smaller families and economy of resources.

ontpelier, Jamaica. CICELY D. WILLIAMS.

PRIMARY TUBERCULOSIS OF THE SKIN

IR.—The article by Dr. Miller (Jan. 3) is most stimuing and thought-provoking. We suspect that it has ened up a field that must call for serious consideration, l it is to be regretted that each case in Dr. Miller's portant series is not described in detail.

The dermatologist is familiar with the primary complex the skin presenting as a hard chancre and soon sociated with regional lymph-node enlargement. Later ere appear lupus nodules in the primary lesion and seation in the lymph-nodes. While it is probably true at other forms of cutaneous tuberculosis are not rmally associated with regional caseating adenitis, the rmatologist would not have regarded such adenitis th caseation as pathognomonic of a primary infection ly. It may well be that he must revise his ideas; but, taneous lesions apart, caseating tuberculous lymphodes are surely common enough apart from primary sions. The point is important, for the suspicion of a imary infection must set in train investigations and eatment of rather elaborate patterns demanded by the imary phase of infectivity.

In a series of 800 patients with tuberculosis of the skin en in the dermatological department at Leeds in the ast twenty-five years, there have been only 18 with a rimary tuberculous complex of the skin. This has led the feeling that the condition is uncommon; but from r. Miller's paper it is clear that patients with primary fections of skin or mucosa may present themselves to variety of departments so that the over-all picture is ot appreciated.

In our simplicity we should have questioned—on the cant evidence in the paper—the validity of regarding he 10 cases with a history of trauma as true primary infections. Other factors would clearly predispose to adenitis, and infection of a wound with tubercle bacilli would favour their passage to the lymph-nodes. Yet the negative Mantoux reaction on admission of the patient who had sustained a head wound in a road accident would favour Dr. Miller's thesis. He will nevertheless appreciate the desire of those interested to have further details of all these 10 cases.

The occurrence of a primary lesion on the skin and in the lung, as in case 2 in Dr. Miller's series, is most interesting. It would seem probable that, as in syphilis, while this is sometimes observed it is likely to be uncommon. The discovery of evidence of a lesion in the lung would generally exclude the probability of a lesion in the skin being a primary complex. The findings in the lungs in the other traumatic cases would be of interest.

The splash of lupus nodules in the site of a primary tuberculous chancre has invariably been seen with our patients; but this feature may follow ordinary chronic warty tuberculosis in the butcher and others, or the ulcerative pyogenic type of lesion that sometimes arises from this mode of infection.

JOHN T. INGRAM
Leeds. STEPHEN T. ANNING.

EVALUATION OF RADIOLOGICAL SERVICES

SIR,—The expansion of radiological services since the end of the war has been in the region of 200% over the whole country and it shows no sign of diminishing. Practically every new advance in medicine and surgery demands increased effort and increased output from radiological departments with a corresponding increase in costs. Since a financial limit has of necessity been applied to the National Health Service, it is essential that the funds available for radiological examinations should be used to maximum advantage in the interests of efficiency and economy. It may not be generally appreciated that in many instances the cost of a patient's X-ray investigations may be greater than the combined cost of the whole of his treatment.

It is known by radiologists that the usual methods of assessing the work done in X-ray departments are unreliable and of no comparative statistical value, and there is general agreement on the need for a more reliable system.

The Nuffield Provincial Hospitals Trust, in collaboration with a number of radiologists, carried out an experiment in what is now called the unit system of recording. The authors of this report emphasise that the experiment was not conducted "over a sufficiently long period to demonstrate the usefulness of their suggestions."

The Faculty of Radiologists, whose help at one period was sought by the Nuffield Trust, had, in the early days of this experiment, realised the difficulties which would arise in applying on a national scale the results of a localised survey.

The faculty is aware of the danger in any such system of wrong inferences being drawn as to the quality of the work done in a radiological department. It has, however, been assured by the Ministry of Health that this is not a matter of controlling the way in which medical work is done but only of recording its amount in a form which makes some allowance for the varying complexity of different examinations. There is no intention of seeking uniformity, which in any case is impossible; but study by individual departments of their own problems as compared with others in the light of these statistics might enable them to raise their own standards of efficiency, while at the same time decreasing costs.

Following publication of the memorandum RHB(52) 130, the Ministry of Health informed the faculty that it was recognised that the unit values might be found to need alteration in the light of experience and would be glad to receive any observations on them which the remaining acid-secreting cells, and the recurrence-rate in Visick's series was nil (Pulvertaft 1952) Though this operation, in skilled hands, may carry a mortality of no more than 4% and gives a high degree of protection against relapse, it is on occasion attended by undesirable side effects described in detail by many writers (Wells and Welbourn 1951, Braun and Stammers 1951, Adlersberg and Hammerschlag 1947)

The tendency to lose weight shown by patients who have had such high resections has been previously mentioned (Johnson 1948), and it was observed that the degree of weight loss appears to be proportional to the amount of stomach removed The "dumping" syndrome, too, is commoner and more severe when radical resection has been used, and we have found its incidence to be correlated with inability to eat more than a very small meal and with complaints of regurgitation of bile

It must be recognised that gastrectomy, without deliberate division of the vagi or their gastric branches inevitably destroys a large part of the vagal supply to other organs, a fact too often ignored by those who have inveighed against vagotomy

Several of our colleagues who use high gastrectomy regularly for all kinds of peptic ulcer have encouraged us to follow their patients along with, and by the same methods as, our own These together with those of our own high gastrectomies which fell into the beginning of the total period under review, before we had both adopted our present policy, amount to 241 cases

We have not explored the mortality in this particular group (there were no deaths among our own few cases), but from a separate study of over 3000 post-war gastrectomies, varying greatly in the proportion resected, we have ascertained that the average mortality has been 4%, being higher where high gastrectomy was routinely used and lower where conservative resection was the rule

MODERATE PARTIAL GASTRECTOMY WITH OR WITHOUT VAGOTOMY

Data about the spontaneous secretion of acid at night, collected from some 400 patients, show that, though duodenal ulcers and some juxtapyloric ulcers are associated with interdigestive hypersecretion of acid, most gastric-ulcer patients have levels of secretion below the average for normal people

Though anastomotic ulcer has been an occasional sequel to gastrectomy for duodenal ulcer, for combined ulcers, and sometimes for prepyloric ulcers it has seldom, if ever, followed even hemigastrectomy when performed for other gastric ulcers Moreover, the investigation into jejunal ulcer conducted by the Association of Surgeons (1935) showed that the patients who developed anastomotic ulcers were the ones with unusually high acidity of their gastric contents We therefore contend that high or subtotal resection is unnecessary for hyposecreting patients, such as most of those with gastric ulcers Not only is a moderate two-thirds resection sufficient for the cure and control of their disease but also it is possibly less dangerous to life and gives better symptomatic results We have found the Billroth I anastomosis most satisfactory in gastric-ulcer patients

Both we and others have found that vagotomy is a successful operation for the cure of anastomotic ulcer, and we therefore judged it likely to prevent them We have therefore felt justified in returning to moderate gastrectomy in hypersecreting patients as well, with the addition of vagus resection to prevent the recurrences otherwise to be expected in a proportion of these cases after a two thirds resection

An investigation by the American Gastroenterological Association into the results of some 2600 operations for peptic ulcer (Jordan 1951) showed that addition of vagotomy to ordinary high gastrectomy was not harmful whereas 91 6% of those who underwent gastrectomy alone survived and were satisfied with the result, in case of gastrectomy plus vagotomy the figure was 94 Since the recurrence rate was negligible with rad gastrectomy alone, it was thought that nothing m was to be gained by the addition of vagotomy We, the other hand, hoped that, by adding vagotomy to moderate gastric resection, we should achieve ulcer cu as dependable as those won by high gastrectomy, a at the same time we should have results as symp matically satisfactory as those which go with m conservative resection

For several years we have been applying a policy peptic ulcer which has implied the use, in nearly all ulcer cases, of either (*a*) two-thirds gastrectomy alone, (*b*) similar moderate gastric resection plus division of t vagi or their gastric branches The results of th operations performed during the five years end December, 1951, are described below

METHOD OF SELECTION

The spontaneous interdigestive secretion rate of ac is determined for each patient by continuous gas suction during twelve night hours The volume of ju in litres multiplied by the titratable free hydrochlo acid in clinical units gives the number of milliequivalen of hydrochloric acid produced in the whole night W have chosen the arbitrary figure of 20 m eq as the le of secretion above which the addition of vagotomy gastrectomy is indicated (Johnson 1951) However, often happens in practice that tubes become blocked aspiration is incomplete for some other reason A hi level of acidity (over 45 clinical units of free hydrochlo acid or over 65 units of total acid) in the bulked juice also adequate evidence of nocturnal hypersecretion, ev though the volume of juice aspirated has not been ve great

Following this rule we have employed moderate part gastrectomy alone for 90% of our patients with gastr ulcers and for 52% of those with duodenal ulcers, wi the addition of vagal resection in most of the other The choice of operations is shown in greater detail in th accompanying tables

Patients with carcinoma in ulcere, benign or malignan tumours, and pyloric stenosis with long since heale ulcers are excluded from consideration, the last name because they were often considered amenable to gastro enterostomy under any policy Patients with anastomoti ulcers after earlier gastro enterostomy were included fo we dealt with them by vagotomy alone or moderat gastrectomy with or without vagotomy, in accordanc with our principles in the "policy" series There was a similar proportion of such patients in the high gastrectomy series

Recurrence of symptoms after earlier gastrectomy is a different problem and could not be included, for the initial operation was sometimes a high resection not able to be modified to bring it into line with our policy, moreover, we are not seeking to show that the addition of vagotomy to very radical gastrectomy can do much to improve its results or to alleviate its occasional ill effects The results of vagotomy used for anastomotic ulcer after earlier gastrectomy will therefore be dealt with separately Patients who had emergency operations for massive hæmorrhage or for perforation could not be assessed in the usual way and submitted to the operation selected accordingly They, too, are therefore left for consideration elsewhere

MORTALITY

The operations used in applying the above policy have had few serious complications, and the mortality has compared favourably with that in any series of subtotal gastrectomies published

Of the 526 patients operated on under the policy during the period under review, 486 had gastrectomies illy arises as right ventricular failure supervenes roxysmal pulmonary symptoms wane. It signifies, er, that the disease process has advanced and now es pulmonary arterioles and myocardium as well ral valve.

homas's Hospital,
ondon, S.E.1.

RICHARD GORLIN.

All who have experience of mitral valvotomy agree nitral incompetence can be present when a systolic ur is absent or insignificant, and the Swedish rs on whose article we were commenting recognise A hypothesis of progressive narrowing of the mitral supported by Dr. Gorlin and by Dr. Wade (Jan. vould be satisfying; but Brock's experience gives for thought. Surgical widening of the mitral-valve ng does not always give the relief we should expect severity of symptoms depended entirely on the e of valvular obstruction. Furthermore, resting ares in the pulmonary artery may apparently be y normal in the presence of disabling symptoms.[5]

. L.

PARONYCHIA

—In his interesting paper (Jan. 17), Mr. Lowden ions circulatory inadequacy as a possible antagonistic r to satisfactory results.

aile reviewing rather over a thousand cases of finger ion[6] I followed up this point. I had expected to as Mr. Lowden suggests, that in the cold vasorictive winter months finger infections would be common and would do less well than during the ner months. I therefore worked out the incidence ises during each fortnight over a period of three , and also the average healing-time of cases during fortnight. I found that, while the differences in ence were not significant, cases were most numerous ine and July and fewest in October and November; s at other times of the year were intermediate. iously, other factors are involved; but these results ld not seem to suggest that winter weather increases incidence of finger infections. The average healing- was found to remain remarkably constant through- all months of the year. It seems, therefore, that e cold no doubt slows down the inflammatory onse, it also slows down the rate at which bacteria ide the tissues.

is noteworthy that in the majority of cases in our es where gangrene developed the patient was diabetic.

anmore, Middlesex.

B. VICTOR JONES.

ERFORATION OF DUODENAL ULCER AFTER BARIUM MEAL

IR,—In your issue of Dec. 27 Dr. de Fonseka cribed a case of acute perforation of a duodenal er immediately after a barium meal. I observed a ular case in 1947.[7]

> uring X-ray examination of the stomach a duodenal er perforated. The radiographs showed an ulcer in ompartment form" in the anterior wall of the duodenal b with a small perforation and a tiny streamlet of barium the outer surface of the bulb. The patient was operated within 3 hours (Dr. Suren). Only a small amount of barium s found in the immediate vicinity of the perforation, ich was closed. The patient made an uneventful recovery.

This case is interesting because of the extreme rarity radiographic records of the course of a perforation. ill more important is the fact that this ulcer showed e "compartment form" with a relatively long and narrow canal leading from the mucosal surface to a small cavity immediately beneath and in the thickened serosa of the duodenal bulb. Professor Deelman,[8] who has repeatedly described this type of ulcer, emphasises that it is only seen in duodenal ulcers of short duration, and is found especially in specimens removed during operations for acute perforation. The danger of perforation in duodenal ulcers of this type is again illustrated by our case, and we learned from it to be extremely careful about patients who show this type of ulcer radiographically.

C. L. H. MAJOOR.

CHILD-WELFARE CLINICS

SIR,—Medical officers working in public-health departments will welcome the account (Jan. 10) of the investigation by Dr. George and his colleagues. It is right that the usefulness of local authorities' work should be questioned from time to time in the light of experience since 1948.

I should like to comment on some of the points raised. It is suggested that the advisory work at infant-welfare centres can be done just as well by health visitors as by medical officers. This of course is true. Indeed, it is often done better by the health visitor because she has an intimate knowledge of the home. This leaves the routine examinations and treatment. Local-authority medical officers commonly feel that their hands are tied when they wish to treat a child at an infant-welfare centre. Lack of therapeutic agents limits the amount of treatment they can give. Moreover, they feel under an obligation to refer the child to the general practitioner.

Dr. George and his colleagues have emphasised that preventive and curative services should not be divorced. A generation of general practitioners is arising who, by training and outlook, are equipped to educate, advise, and treat patients. By all means let them take over the work at infant-welfare centres. There are, however, some difficulties. Practising at the local-authority clinic, they would be consulted by mothers whose children were registered with one of a number of practitioners in the neighbourhood. What treatment other than that already being given could they prescribe for children not on their own lists? With health centres and an extension of group practice, this difficulty would not arise; but these ideals are still unrealised.

An alternative is the loaning of health visitors to practitioners to help them conduct their own infant-welfare centres at their surgeries. Some general practitioners are already setting aside one or two afternoons a week when they see babies and toddlers only. The drawback to this suggestion is that it leaves out proprietary foods—the reason for half the attendances at infant-welfare centres!

What is clear is the need for bold experiment along various lines, and for realisation that the closer integration of general-practitioner and local-authority services will benefit the children.

Smethwick, Staffs.

JOHN S. OWEN
Senior Assistant Medical Officer of Health.

SIR,—The discussion in your columns on the future of the local-authority child-welfare clinics and the clinic medical officers has arisen at a time when these clinics may be regarded as an extravagance by local authorities who are seeking to curb their expenditure; in fact, the Birmingham City Council about six months ago were not going to provide new welfare centres on the new housing estates because there was a prevailing opinion that the work carried out at the centres with regard to maternity could be done by the general practitioners and a limited

Bayliss, R. I. S., Etheridge, M. J., Hyman, A. L. *Lancet*, 1950, ii, 889.
Scott, J. C., Jones, B. V. *J. Bone Jt Surg.* 1952, 34B, 4.
Schulte, N. J., Majoor, C. L. H., Suren, Th. J. J. *Ned. Tijdschr. Geneesk.* 1948, 92, 3940.

[8] Deelman, H. T. *Ibid*, 1938, 82, 1190; 1942, 86, 1040, 1821; 1947, 91, 1769, 2234.

are given in the tables, but their significance to the patients is best assessed by considering the categories into which the patients placed themselves in answering the last question noted above

In the radical gastrectomy group 89% of the patients followed put themselves in one of the top two categories (cured and normal, or greatly improved) 8% were a little better and considered the operation worth while, and 2% did not feel any better for it at all Of the patients in this group 33% had gained weight up to or above their preoperative level and had been altogether free from any gastro intestinal or related symptom

TABLE III—AGE-DISTRIBUTION

Age group (yr)	Radical gastrectomy		Policy group	
20–29	5%	Under 50 58%	7.5%	Under 50 58%
30–39	21%		15.5%	
40–49	32%		35%	
50–59	23%	Over 50 42%	28%	Over 50 42%
60–69	14%		12%	
70 or more	5%		2%	

In the "policy" group 95% of patients selected one of the top two categories, 4% considered themselves a little better, and 1% were no better at all Of these patients, 52% had gained weight and been completely symptom free

It is clear that both approaches have achieved a high order of success Though the age and sex distribution and length of follow-up were similar in the two groups, it is, of course, impossible to know whether they were strictly comparable as regards "curability" But the claim that our policy has been vindicated is based less on these appearances of slightly superior results than on the fact that they have been won at so low a cost in lives Our preference for moderate gastric resection may be one of the factors which has helped us to achieve this low mortality

Comparison of the results of each operation used within the selection policy as regards success in preventing recurrence and curing ulcer disease would not be valid, for each was used for a different purpose However, it is interesting to compare the incidence of side effects These are enumerated in table II, and it is seen that the addition of vagotomy to moderate partial gastrectomy has made no significant difference to the incidence of any symptom except possibly "wind" pain, though when high gastrectomy is used this symptom is more frequent still Compared with two thirds gastrectomy or limited resection plus vagotomy high gastrectomy is seen to carry a greater risk of "dumping," bilious regurgitation, and weight loss Diarrhœa was so unexpected a sequel to vagotomy alone that its occurrence received much publicity in the early days of that operation In our experience it was often noted during the first few weeks after vagotomy alone, and 3 of the 108 patients submitted to this operation were still having intermittent diarrhœa three months and later after operation It is therefore interesting to observe that only 3 patients complained of this symptom out of the 246 followed after vagotomy plus gastric resection and that there were also 3 among the 241 submitted to low gastrectomy without deliberate vagotomy, and 10 among the 222 who had high gastrectomies

The last question put to the patients in the questionnaire was "If you were to go back to before your operation, but knowing what you now know about the effects it would have on you, would you again choose to undergo it?" 99.6% of our patients replied "Yes," and though asked not to do so, a great many wrote in such things as "most definitely," "A thousand times yes," or "Yes, but twenty years sooner"

DISCUSSION

Division of both vagi or of the whole of their gast branches has proved efficient in controlling excess interdigestive acid secretion However, when th manœuvre has been used alone in duodenal ulcer patien the symptomatic results have been marred by the effec of scarring and gastric retention Because vagotomy h not proved to be a surgical *mend all, its omission fro* the surgeon's repertoire has been suggested, but in o view this would be equivalent to throwing a spann away because it cannot do the work of the who tool-kit

We are *in full agreement with Ogilvie (1952)* when urges that no further use should be made of vagotom alone in the treatment of duodenal and gastric ulcer but we cannot endorse his statements that the vagi nerves are divided for gastric pain, that hormonal jui is unaffected, and that nervous secretion is harmless

In 1915 Sippy drew attention to the excessive continuo interdigestive or "resting" acid secretion characteristic *patients with duodenal or anastomotic ulcers now consider* to be mainly neurogenic He regarded this as the mo *dangerous element of gastric activity*

It has been repeatedly shown that vagotomy reduces th resting secretion by some 80% (Dragstedt 1945, Moore et a 1947, Orr and Johnson 1947) It also diminishes by som 70% the acid response to test meals and histamine injectio (Stein and Meyer 1948 Farmer et al 1951, Johnson 1950)

It has not been with any idea of interrupting pain pathway that we have used vagotomy Indeed, pain conduction fro the ulcerated area has been shown to be unimpaired b division of the vagi (Foerster 1927, Moore et al 1947, Johnso 1947)

Ogilvie cites division of branches of the vagi as on *of the criteria of a satisfactory gastrectomy*, though h divides them only to give greater mobility to the gastri remnant In our opinion routine high division of th vagi or of their gastric branches in all gastrectomies, without regard to the patient's pattern of secretion, ma be harmful in those whose stomachs are already hypotoni and hyposecreting Moreover, we believe with Butler and Capper (1951), that every effort should be made to preserve the natural supports of the stomach, even though this may make the operation slightly mor difficult

It has been suggested that patients who have had vagotomy plus pylorectomy are reduced to complete and permanent achlorhydria, and that this might increase the dangers of infection and of the supervention of carcinoma *From many hundreds of secretion investi*gations we conclude that there is no significant difference between the effects on gastric secretion of two thirds

PRACTICAL PENICILLIN

R,—Mr. Cohen's article last week must not, I think, llowed to pass without comment. I will not linger nis ingenuous suggestion that general practitioners not yet acquainted with aqueous procaine penicillin. having myself treated very many more than his cases (of which 35 were apparently not followed I must disagree with him on several points.

n the first place, whilst he has shown that a single ction of 1,500,000 units of aqueous procaine penicillin ml. will produce significant blood-levels for about e days, there is little doubt that a daily injection of .000 units will produce a higher average level. Since entially serious infections, such as those of the d, breast, or middle ear, should be seen daily for the few days, there is no difficulty in a daily injection. the second place, the indiscriminate use of penicillin all minor sepsis is bad medicine, because less sensitive anisms may in this way become penicillin-resistant: applies especially to staphylococcal infections skin, such as boils and furuncles; and these in any e usually respond not much better to penicillin than simple local treatment. In the third place, Mr. Cohen kes no mention of bacteriology, and the type of ecting organism determines to a large extent the ount of penicillin required. For example, streptocal tonsillitis is cured rapidly with one or two injections 500,000 units, whereas carbuncles usually require ger doses over several days. Fourthly, I cannot agree h his generalisations on otitis media. Acute ear ections respond nearly always extremely well to nicillin; but ears which have been discharging for nths, presumably having become secondarily infected, on the whole respond poorly. Fifthly, the graphs illustrating percentage rates of cure are not comparable, since cases seen at hospital are obviously selected ones as compared with those seen in the surgery.

On one point I agree with Mr. Cohen: it is important to keep patients away from hospital outpatient departments—but for the patients' sake rather than the departments'.

Shrewsbury. John C. Ryle.

THE VASOMOTOR DISTURBANCE IN PINK DISEASE

Sir,—In his paper on the vasomotor disturbance in pink disease,[1] Dr. Vulliamy repeats the fallacy of Lewis and Landis[2] that there is no structural narrowing of small arteries or arterioles if their strong contraction can be released to full dilatation. Such dilatation shows only that elasticity has been retained, and not necessarily that structural narrowing, such as that in acrocyanosis,[3] is absent. A simple mathematical treatment[4] shows that narrowing, even though considerable when the vessel is fully contracted, will be negligible when it is well expanded.

Warwick. Edward S. Stern.

Obituary

ROBERT VEITCH CLARK

M.A., M.B., B.Sc. Edin., D.P.H.

Dr. Veitch Clark, who died on Jan. 20 at the age of 76, was in charge of Manchester's public-health services for twenty strenuous and progressive years, and had previously won a high reputation at Croydon.

He qualified at Edinburgh in 1901, having already obtained the M.A. in 1896, and the B.SC. in 1900. After holding resident hospital appointments he became lecturer in physiology in the University of Leeds. Here he developed a strong belief, to which he always held, in the importance of scientific laboratory work in the prevention as well as the cure of disease. His interest in preventive medicine led him to take the diploma in public health at Oxford in 1907, and he returned to Leeds as assistant medical officer of health and lecturer in public health. He remained there until he was appointed medical officer of health for Croydon in 1913. His promotion to the post of medical officer for health of Manchester came in 1922.

[Schmidt, Manchester

In Manchester he at once turned his attention and energies to the many public-health problems of a large industrial town. In 1924 he was appointed honorary secretary of the Manchester and District Regional Smoke Abatement Committee, a voluntary association of official representatives of local authorities in South-east Lancashire which acts in an advisory capacity in controlling smoke nuisance. In the same year, in accordance with recommendations of the Ministry of Health, the Manchester Committee on Cancer was formed. The first move was the formation of a provisional committee, and Dr. Veitch Clark was appointed the first chairman. He held this position until he retired. The committee conducted propaganda, experimental research, treatment, aftercare, and follow-up of patients, and statistical recording of cases. Particular attention was paid to mule-spinners' cancer and to experimental research on the carcinogenic properties of the lubricating oils used in the cotton-spinning industry. Seven years later the

from one of the early Rochdale cases and had been passed twice on the chorioallantois of chick embryos The smallpox strain had been passed 8 times since its isolation from a case of variola major in 1946 The vaccinia strain was recovered from the vaccination "take" on a young adult (Lister Institute lymph) and had been passed 8 times on the chorio allantois The cowpox strain was isolated in 1937 from lesions on the hands of a cowman and had been passed on 20–30 rabbits and 16 times on eggs

Complement fixation Tests

To sera in doubling dilutions from 1/5 upwards were added 3 M H D (minimum hæmolytic dose) of complement and an equal volume of antigen (0 2 ml) These mixtures were left in the refrigerator overnight, and next morning 0 4 ml of sensitised sheep red cells was added to each tube The tubes were placed in a water bath for thirty minutes and then allowed to stand for a further two hours at room-temperature before the results were read The titre was taken as the initial dilution of serum in the last tube to show less than 50% hæmolysis Antigens used were clear saline extracts of chorio-allantoic membranes of chick embryos which had been harvested three days after being infected with alastrim, variola, vaccinia, or cowpox virus These antigens were titrated beforehand against dilutions of rabbit immune sera, that dilution of antigen was chosen which was the highest to give maximum fixation with 1/10 to 1/80 dilutions of immune rabbit serum With egg membrane antigens the optimal antigen dilution was usually 1/15 to 1/25

Antihæmagglutinin Tests

The hæmagglutinin for these titrations was prepared only from vaccinia infected egg membranes Extracts from membranes infected with the other three viruses gave irregularly low titres of hæmagglutinin when tested against susceptible fowl red cells and were not used The blood cells from a number of fowls were tested and those birds whose red cells were found suitable were selected as blood donors for routine work Blood from a wing vein was taken into citrate The cells were washed three times and suspended in buffered saline to give a 1% suspension for the tests, 1% inactivated normal rabbit serum being added as a stabilising agent Saline extracts of vaccinia infected chorioallantois were titrated against fowl cells to find the minimum hæmagglutinating dose, and four times this amount in a volume of 0 25 ml was used in testing the sera from alastrim patients Doubling dilutions of serum from 1/10 upwards were mixed with 4 hæmagglutinating doses of antigen in a series of tubes These were placed in a water bath at 37°C for one hour, 1% suspension of fowl cells was then added The tubes were shaken after twenty minutes at 37°C and then kept for another hour at 37°C They were left for one hour at room temperature before the results were read The titre of the serum was taken as the highest dilution which prevented all but a trace (±) of agglutination of the red cells

Neutralisation Tests

The technique used has been described by McCarthy and Downie (1948) The virus suspensions had been prepared from infected egg membranes and partially purified by differential centrifugation The virus preparations were titrated by inoculating tenfold dilutions on the chorioallantois of groups of fertile hen eggs which had been incubated for twelve days After three days' further incubation the eggs were opened and the number of lesions present on the membranes noted For tests with the sera, that virus dilution was chosen which would give between 50 and 200 lesions on the chorioallantois All the sera were tested against alastrim virus A 1 in 2 dilution of serum was mixed with an equal volume of the selected dilution of virus and after forty minutes at room-temperature each mixture was inoculated on 5 or 6 eggs Three days later the membranes were examined and lesions counted The percentage neutralisation was obtained from the average number of lesions per membrane as compared with the average number of lesions resulting from the inoculation of the same amount of virus mixed with normal sera from non-vaccinated individuals One serum was also tested by this technique in dilutions against each of the four viruses

RESULTS

Results Obtained by Three Methods of Detecting Antibody

The results of the tests on 21 sera are shown in table I It should be noted that the complement fixing titres shown were obtained against alastrim antigen and that the neutralising titres were measured against alastrim virus For the determination of antihæmagglutinin a vaccinia antigen was used for the reason given under "methods" It has been shown (Chu 1948) that the complement-fixing antigen and the hæmagglutinin of vaccinia are different and that neutralising antibody is not the same as that concerned with complement fixation It is therefore not surprising that there is not complete correlation of the results of the three tests with individual sera The results, however, show that from the tenth day of illness all sera were positive to each of the tests The neutralisation test using only a single dilution of serum (1/2) does not give very accurate quantitative results Such assessment of neutralising antibody can be better made by testing dilutions of the serum against a constant amount of virus (see table IV) Estimations of this kind on all the sera would have required a larger number of eggs than could readily be handled in our laboratory

Time of Appearance of Antibody

By the complement-fixation technique antibody was not found in the four sera obtained before the tenth day of illness (table I) Antihæmagglutinins were found in the serum taken on the ninth day but not in the three taken earlier The neutralisation test, however, gave a positive result with the serum taken on the fifth day and those taken from the ninth day onwards From fairly extensive experience of this type of test we have found that more than 50% neutralisation is significant, while less than this

Notes and News

W.H.O. FINANCES

executive board of the World Health Organisation has iscussing in Geneva the financial difficulties due to in the funds provided by the United Nations Technical nce Board for part of the Organisation's work. These which had been fixed at $10 million for 1953, may be l to $5 million. The chairman of the executive board. Jafar, said that no sharp distinction could be drawn n W.H.O.'s regular programme (financed by the regular udget of nearly $9 million) and its Technical Assistance mme for Economic Development. Social develop- economic progress, and health improvement were rable, and to abandon or postpone projects already in ion, or even well advanced, would, in Dr. Jafar's do incalculable harm to the whole W.H.O. programme. cussion, a reduction in the administrative machinery I.O. was urged; and some members felt that continuity ng-term planning were needed to allow the Technical ance Board to forecast more accurately the funds it have at its disposal. Mr. David Owen, executive nan of the Technical Assistance Board, said that many ments had not yet fulfilled their 1952 pledges to bute to his board's funds—hence the cuts that had been ary in all parts of its programme. But he hoped that end the gap between the sum expected and the amount ed would not be as great as was feared.

RESEARCH PRIZES

some time past the South West Metropolitan Regional tal Board, like some of the other boards,[1] has had a ch committee which supports investigations with the at its disposal. The board has now gone a step further by ig prizes to encourage "minor items of clinical research." year nine prizes of £100 each will be offered—three for ltants and senior hospital medical officers, three for registrars and registrars, and three for house-officers. noney for this purpose will come from regional research , which are supplied from the Central Endowment ; and the board has apparently taken this step because lises that members of its staff may hesitate to apply lvance for grants to aid work that is not of major rtance.

spital management committees have power to organise own research funds; and Dr. Avery Jones[1,2] has pointed that these funds can foster "small growing-points of ledge in the regional hospitals." The South West opolitan Board, it seems, is pursuing the same objective different way.

ROCKEFELLER GRANTS

E Rockefeller Foundation has made a grant of £10,000 niversity College, London, for the continuation of studies the selection and training of medical students. The will be done in the anatomy department by Miss M. L. ison, PH.D., under the direction of Prof. J. Z. Young. The foundation has supported preliminary work during last five years, and some of the results have been published ur columns.[3] One outcome of the earlier work[4] has been development of free group discussions as a technique to plement the usual methods of teaching in the lecture- atre, the dissecting-room, and the practical class. The n aim of these discussions is to help to develop skill in rate and comprehensive observation, the precise use of guage, and the weighing of evidence. They are conducted way designed to encourage the students to become aware he preconceived ideas which determine how they approach blems, and to examine their usefulness. The discussions recorded on tape, and students can listen to them again l to those of other groups. It is thus possible to get a ter understanding of some of the difficulties of thinking arly which crop up in all groups. The teachers' contribu- ns to the discussion can be studied and their effectiveness essed. With the coöperation of a psychologist, it is ned later to make some objective assessment of the results this teaching method. The discussions lead to the free change of ideas, and a broadening of the students' experience of other people. The students get practice in expressing their own ideas quickly and clearly, in understanding other people's, in giving and accepting criticism, and, in general, in handling the "human," as well as the scientific, side of a doctor's job.

The foundation has also made grants to Prof. W. I. B. BEVERIDGE towards his coming visit to the United States, during part of which he will be visiting professor in the department of bacteriology at Ohio State University; to Dr. ANDREW TOPPING, dean of the London School of Hygiene and Tropical Medicine, for the purpose of observing teaching methods and the practice of public-health administration in the United States and Canada; to Dr. ALEXANDER MAIR, of the University of St. Andrews, for observing teaching methods in public health in the United States and Canada; to the University of Oxford for the purchase of apparatus and supplies for neurophysiological research by Dr. E. M. VAUGHAN WILLIAMS, of the department of pharmacology; and to the University of Manchester for the purchase of laboratory equipment for the use of Dr. S. W. STANBURY in the department of medicine.

PHILOSOPHIC APPROACH TO PSYCHIATRY

Dr. Harold Palmer,[1] faced with the scientist's duty of integrating his concepts and the psychiatrist's duty of coping with his patients, finds himself hampered by the lack of a common language—let alone a common outlook—among the many disciplines with which his specialty has commerce. At one point he encounters neurologists engaged in describing and measuring anatomical and physiological mechanisms, at another psycho-analysts concentrating on mental events, at another behaviourists who have agreed to leave mental events entirely out of their calculations, and at another those who have concepts which they relate to the term "soul." In such awkward company channels of communication are apt to run sluggishly, and Dr. Palmer is quite right to try to open them up: though non-philosophic readers may wish he had done it without the use of terms from yet another discipline, and one notoriously difficult for beginners.

Some proleptic basic assumptions, he suggests, are necessary to the theory and practice of psychiatry (and it is surely an interesting illustration of our semantic entanglements that "proleptic" no longer has anything—except its root—in common with "epileptic"). He assumes, then, for practical purposes, that there is life, and that one aspect of living human beings is connoted adequately by the term "mind"; there are also awareness, experience, knowledge, memory, and introspection. Moreover human beings are either awake (conscious) or asleep; and conscious human beings are "'experiencers' and constitute the 'subject' in a total biological field whose 'objects' are determined in part by their biological relevance and in part by the subject's attention." He thinks of the subject as composed of "the 'self' and its subsystems," and he holds the self to possess a bodily and a mental aspect. Selves communicate by means of symbols, and symbols possess meaning for minds. "Mind is the name we employ to signify both the territory in which we operate with symbols as symbols, and the faculty whereby these operations take place." He also assumes that human minds resemble one another, and that men with the same racial, social, temporal, linguistic, and educational background will tend to collect a similar meaning from any given set of symbols.

Psychiatry, then, concerns itself with "selves"; and mental disorder, whatever its cause, is associated with dislocation of a "self" and a "self-image." A science of "selves," he suggests, is "the only philosophically unassailable discipline within which the psychiatrist can manipulate his terms without offences against logic." It allows him to establish a framework of reference for data from studies of the anatomy, physiology, and pathology of human tissue, studies of the behaviour of institutions, groups, and societies, and studies relating to the notion of "soul" and the notion of purpose (for which Freudian psycho-analysis, being too narrowly mechanistic and deterministic, does not, he thinks, make sufficient allowance).

He suggests that any contribution which the psychiatrist brings to the understanding of human nature is in the order of that made by the novelist, dramatist, or practical man, rather than that made by the scientist. This does not hold, however, when the psychiatrist is engaged in treatment; for then he is invested with special responsibility, and is accountable at law for his acts.

Faced with so many claims on his capacity, a man may well begin to look critically at the training he has received in

ously Although the test for antibody by complement-fixation and antihæmagglutinin estimation may be negative in the first week of illness, other more reliable diagnostic methods give positive results at this time The detection of virus in skin lesions by egg-culture techniques, or of virus antigen by complement fixation, are always to be preferred in the early stages of the illness In recently vaccinated patients they are the only reliable laboratory methods at all stages of illness The antibody in the serum of alastrim patients was no more specific than that in the sera of artificially immunised animals, it reacted practically to the same titre with the viruses of alastrim, variola, vaccinia, and cowpox The isolation of virus from the patient provides the only laboratory method of distinguishing smallpox and alastrim from generalised vaccinia, the distinction between smallpox and alastrim still rests on clinical and epidemiological considerations

SUMMARY

21 sera from 19 alastrim patients who had not previously been vaccinated were examined for antibody by complement fixation, hæmagglutination, and neutralisation techniques The neutralisation techniques using the pock-counting method on the chorioallantois of chick embryos was the most reliable, and the antihæmagglutination method was rather more sensitive than the complement fixation test

All three methods gave positive results on sera taken on the tenth day or later

The sera fixed complement equally well with antigens prepared from egg membranes infected with the viruses of alastrim, variola, vaccinia, and cowpox In neutralisation tests also, the sera were equally active against the four viruses.

We are indebted to Dr J Innes, medical officer of health of Rochdale County Borough, for information about the patients from whom blood was collected

THE METHOD OF ADMINISTERING DICOUMAROL

CHR J BJERKELUND
M D Oslo
ASSISTANT PHYSICIAN, OSLO MUNICIPAL HOSPITAL

IN the administration of dicoumarol care must be taken to avoid hæmorrhage on the one hand and ineffective treatment on the other

The incidence of hæmorrhage in some published series has been so great that dicoumarol has been discredited as dangerous Hæmorrhage has usually been observed in 5% or 6% of hospital patients, two thirds of the hæmorrhages being mild and a third severe (Allen et al 1947, Allen 1948, Nichol 1950, and others) Some of the hæmorrhages have been fatal (Duff and Shull 1949, Nichol 1950, and others) In prolonged treatment of ambulant outpatients the incidence of hæmorrhage has been still greater, up to 15% (Olwin 1949)

One reason why hæmorrhage occurs so often is that there is still considerable disagreement about how to determine the requisite dosage

Two main methods of administering dicoumarol are used at present (1) intermittent dosage, and (2) daily maintenance dosage

Intermittent dosage consists in giving relatively large doses of dicoumarol at intervals of up to 10-12 days How frequently the doses must be given depends on the individual patient's response to dicoumarol Each single dose should be large enough to reduce the prothrombin value to the therapeutic range and keep it there for several days The next dose is given when the prothrombin value has again increased above a certain level As the effect of even a large dose of dicoumarol is seen only after a certain time lag, the effect of each new dose will usually be delayed in relation to the often rapidly increasing prothrombin value Hence the prothrombin values are likely to vary widely, the greatest variations being observed in those patients who metabolise dicoumarol rapidly and therefore require large and frequent doses This method is especially used in the U S A, and has recently been enthusiastically recommended by Shapiro and Weiner (1951) who hold that the danger of overdosage, through accumulation of dicoumarol in the body, is least when this method is used They also claim that *intermittent dosage makes it easier to maintain* a stable and effective concentration I do not agree with this opinion, for reasons discussed below

Maintenance dosage aims at keeping the prothrombin value most nearly constant in the optimal therapeutic range by *giving daily doses in amounts varying according* to the patient's tolerance for dicoumarol This method is most commonly used and I regard it as the only practicable one when treatment of the ambulant patient has to continue for a long time It has, however, proved difficult in practice

This is evident from the many different dosage schedules published *Greatly varying initial doses have been given* In continuing treatment, most physicians have decided the particular day's *maintenance dose according* to the prothrombin value (given in seconds, percentages, or prothrombin index) which has been determined the same morning Some authors have divided the prothrombin scale schematically into intervals and recommend definite *doses for each interval* the lower the prothrombin value the smaller the dose Usually, in schedules outlined no consideration is given to whether the prothrombin value is tending to rise or to fall In other words, the dosage is determined *only from the day's prothrombin value* without regard to previous days' values As a guide for other workers dosage schedules like these have little value Dosage schedules based on the prothrombin time (in seconds) or on the prothrombin indices are valueless unless one uses not only the same method but also the same type of thromboplastin as the originator The relation between a given prothrombin time (or prothrombin index) and the prothrombin value, expressed *as a percentage of normal*, depends not only on the activity of the thromboplastin but also on the type of thromboplastin used (*Owren* 1947, 1949)

The varying nomenclature and methods and the many different dosage schedules have created uncertainty about the administration of dicoumarol Those seeking information can easily become confused and may overlook the important basic point of the treatment I propose to state here the most important principles of dicoumarol treatment and *to describe* a rational maintenance dosage originally introduced in Norway by P A Owren

To assure the rational administration *of dicoumarol* three conditions are necessary

(1) An exact and quick method of estimating prothrombin and a laboratory with the necessary equipment and a staff familiar with the method

(2) The physician who determines the dosage must have theoretical knowledge and preferably also practical experience *of the effect of dicoumarol on man*

(3) Quick and dependable contact between laboratory, administering physician, and patient

Royal College of Physicians of London

Dr. W. R. S. Doll will deliver the Milroy lectures on Tuesday and Thursday, Feb. 10 and 12, at the college, Pall Mall East, S.W.1, at 5 P.M. He will speak on Bronchial Carcinoma—Incidence and Ætiology.

Royal Society of Medicine

Mr. Philip Wade has been appointed librarian of this society. Mr. Wade has been sub-librarian for the past three years.

North of England Obstetrical and Gynæcological Society

The following officers have been elected for 1953: president, Mr. D. Currie; hon. treasurer, Dr. C. H. Walsh; hon. general secretary, Mr. H. Agar; hon. reporting secretary, Mr. S. Bender.

Chadwick Public Lecture

Dr. George Decharneux (Liège) will deliver a lecture at the Royal Society of Tropical Medicine and Hygiene, 26, Portland Place, London, W.1, on Tuesday, Feb. 24, at 2.30 P.M. His subject is to be Industrial Medicine and Hygiene in Belgium.

Course in Tropical Hygiene for Laymen

The annual course in tropical hygiene for laymen will be held by the Ross Institute this year from Monday, July 20, to Friday, July 24. Further particulars may be had from the institute at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1.

International Hæmatology Congress

The fourth European Congress of Hæmatology will be held in Amsterdam from Sept. 8 to 12. The English speakers will include Dr. J. V. Dacie, Dr. J. F. Ackroyd, and Dr. C. C. Ungley. The main subjects chosen for discussion are: Immuno-hæmatology, Erythropoiesis and Hæmoglobin Metabolism, Acute Leukæmias, Lymph-gland Puncture, Thrombocyties, and the Physiology and Pathology of Coagulation. Further particulars may be had from Dr. M. C. Verloop, secretary of the congress, Maliesingel 15, Utrecht, Holland.

Chronic Rheumatic Diseases

A weekend course on these diseases will be held at the rheumatism unit of St. Stephen's Hospital, Fulham Road, London, S.W.10, on March 21 and 22. Dr. Peter Bishop will give the opening lecture on the Endocrine Aspects of the Chronic Rheumatic Diseases, and other speakers will include: Dr. Francis Bach, Dr. Grace Batten, Dr. Raymond Daley, Dr. Phillip Ellman, Mr. H. E. Harding, Dr. F. Dudley Hart, Dr. J. H. Jacobs, Dr. J. A. Purser, Dr. F. Sargent, and Dr. G. Signy. Further particulars may be had from the secretary of the Fellowship of Postgraduate Medicine, 1, Wimpole Street, W.1.

Royal Sanitary Institute's Congress

The institute will hold its health congress this year at Hastings from April 28 to May 1, under the presidency of Lord Eustace Percy. The speakers will include Dr. J. F. Warin and Dr. R. Scott (section of preventive medicine); Dr. B. E. Schlesinger, Dr. F. J. W. Miller, Dr. Maurice Woods, Dr. Dorothy Egan, and Dr. Mary Hellier (section of maternal and child health); Dr. Charles Wilcocks and Dr. D. Khatri (section of tropical hygiene); and Dr. Andrew Meiklejohn, Dr. C. O. S. Blyth Brooke, and Dr. J. G. Billington (section of occupational health). Copies of the programme of the congress can be had from the secretary of the institute, 90, Buckingham Palace Road, London, S.W.1.

Registration of British Medical Graduates in Victoria, Australia

Now that the full provisions of the Medical Act, 1950, of Great Britain have come into operation, an amendment of the Victorian law is necessary to restore reciprocity of registration. As Victorian law is now framed the necessity for Victorian graduates in medicine to produce the further evidence of experience when seeking registration by the General Medical Council of Great Britain and Ireland makes it impossible for the Medical Board of Victoria legally to recognise qualifications in medicine gained in Great Britain and Ireland. The Victorian government are considering the necessary amendment, but meanwhile the Medical Board of Victoria intends refusing applications for registration, in the

Association of Whole-time Salaried Specialists

The annual general meeting of this association will be h at the Royal College of Surgeons, Lincoln's Inn Fiel London, W.C.2, on Friday, Feb. 20, at 4.30 P.M. The ann dinner will take place the same evening at the college. F particulars may be had from the secretary of the associati 45, Lincoln's Inn Fields, W.C.2.

Assistant Medical Officers' Claim

At a meeting of committee C of the Medical Whit Council on Jan. 22, the staff side put forward the claim an adjustment in the remuneration of assistant medi officers. Agreement was not reached, and the staff si requested that the matter should go to arbitration. T management side agreed to this course.

An Indian Chest Institute

The Vallabhbhai Patel Chest Institute at New Delhi w opened on Jan. 12 by the Indian health minister. T institute has grown out of the chest department of De University, and the World Health Organisation has recogni the department as a training centre for its fellows fr the south-east Asia region.

Poisons Rules

The Home Office draws attention to the Poisons (no. Rules 1952,[1] which came into operation on Jan. 1. Th rules make good the omission from the first schedule to Poisons Rules 1952[2] of dinitronaphthols, dinitrophenols, a dinitrothymols.

Lady Tata Trust

The trustees of this fund invite applications from inve gators of any nationality, working in any country in which is possible to make payments, for grants, scholarships, fellowships for research on diseases of the blood, with spec reference to leukæmia. In view of the affinity betwe leukæmia and other forms of neoplastic disease, candida who wish to undertake research on any aspect of malign disease which may throw incidental light on the rela problem of leukæmia will be eligible.

Grants are made for research expenses or to provide scientific technical assistants for senior workers. Scholarships (at the rate £600 per annum) are awarded for the personal remuneration workers carrying out approved research under suitable directi In addition, the trustees may award one or more fellowships (£1 p.a.) to workers with considerable research experience. Furt particulars may be had from the secretary of the scientific advis committee, c/o Medical Research Council, 38, Old Queen Str London, S.W.1. Applications must be submitted before March 1953.

Administrative Costs of Executive Councils

The Minister of Health has informed executive councils England and Wales of the cost per head of population of administrative expenses of each council in the year 1951– Among 49 English county and combined county and coun borough executive councils the cost per head was highest the Scilly Isles (2s. 10d.) and Westmorland and the Soke Peterborough (each 1s. 9d.), and lowest in Gloucester city a county, Berkshire, and the East Riding of Yorkshire (ea 10d.); among these councils the average cost per head w 1s. 2d. Among 74 English county-borough executive counc the cost per head ranged from 2s. 2d. in Chester to 11d. Coventry and Huddersfield; the average cost among th councils was 1s. 4d. Among 12 Welsh county and co bined county and county-borough executive councils cost per head ranged from 2s. 2d. in Cardigan to 10d. Glamorgan, with an average of 1s. 6d.; and among 3 Wel county-borough executive councils the cost per head w 1s. 5d. for Cardiff, 1s. 4d. for Swansea, and 1s. 6d. for Merth

---

EMERGENCY BED SERVICE.—In the week ended last Mond applications for general acute cases numbered 2191. The proporti admitted was 73·48%. A red warning was issued last Tuesd

DR. WILLIAM PICKLES, of Aysgarth, is sailing on Feb. 26 for So Africa, where he has been invited by the University of Cape To to give a series of lectures. He will be away 10 weeks.

The photographs of the new Central Public Health Laboratory Colindale (*Lancet*, Jan. 24, 1953, p. 190) should have been attribut to Cecil Walden, Ltd.

---

1. Poisons (no. 2) Rules 1952 (S.I. 1952 no. 2268). H.M. Station Office. 2d.

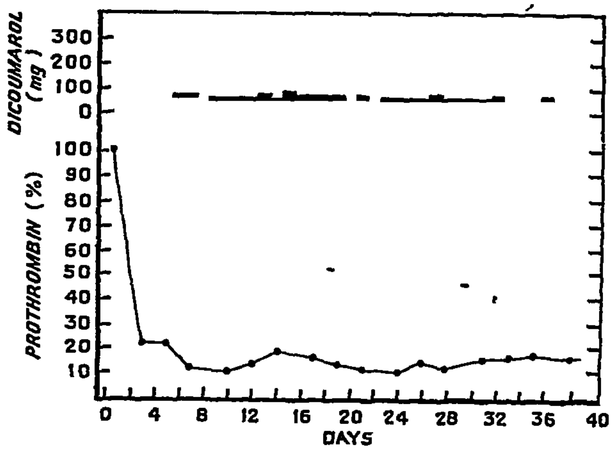

Fig 2—Adjustment of dosage of dicoumarol according to effect on prothrombin in a man, aged 73, with coronary thrombosis and moderately resistant to dicoumarol

previous doses of dicoumarol that we see on the curve because of the prolonged cumulative effect of dicoumarol What we aim at with the dosage is to reduce the prothrombin value as quickly as possible to the therapeutic range, which seems to lie between 10% and 30% The next step is to learn the patient's tolerance towards dicoumarol—in other words, to establish the daily maintenance dose needed to keep the prothrombin value as nearly constant as possible in the therapeutic range Experience shows that the daily maintenance dose can vary from about 20 mg to about 150 mg We can obtain the first impression of the patient's requirement of dicoumarol by studying the effect of the initial dose after two or three days, as already mentioned If the prothrombin value diminishes rapidly and extensively it indicates that the patient is relatively sensitive If the effect is slow and weak, one can count on the patient being resistant As one continues the dosage, the curve will constantly show the effect of the doses which have already been given The practical method of determining the dosage can be most easily understood from illustrative cases in which the adjustments of the dosage were based on fluctuations in the curves

Fig 2 shows the progress of the treatment of a moderately resistant patient The prothrombin value fell evenly to the therapeutic range and the correct maintenance dosage was quickly reached

Figs 3 and 4 are from two patients, one moderately sensitive and the other very sensitive The prothrombin values of both fell rapidly to the therapeutic range In the first patient (fig 3) the dose was therefore omitted on the fourth day, and during the rest of the course the prothrombin value was kept in the therapeutic range with daily doses varying between 37 mg and 50 mg In the second patient (fig 4) the prothrombin value fell (in spite of small doses on the third, fourth, and fifth days) to 6%, but climbed above 10% when dicoumarol was withheld for a couple of days After small doses of 37–50 mg daily for five days the prothrombin value again fell (to 3%) and it remained too low for eight days in spite of intravenous vitamin K No complications were observed

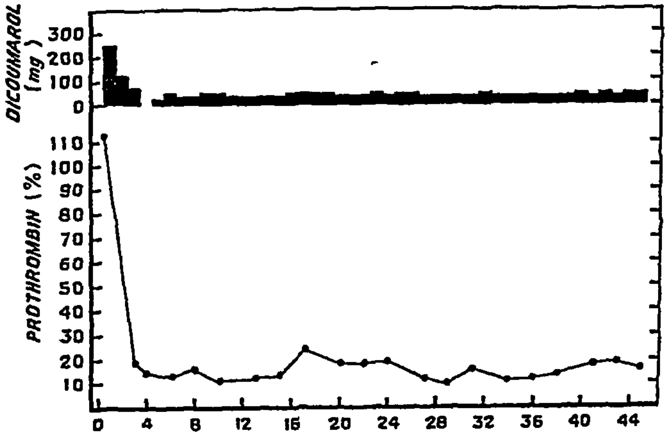

Fig 3—Adjustment of dosage of dicoumarol according to effect on prothrombin in woman, aged 66, with thrombosis of a femoral vein and moderately sensitive to dicoumarol

Fig 5 shows the course in a very resistant patient With the usual initial doses, the prothrombin value had decreased very little at the end of the first three days During the next ten days very large doses, 125–200 mg, were given daily, and the prothrombin value fell relatively slowly to the therapeutic range, taking about a fortnight to get below 20% As the prothrombin value continued to fall, the dosage was reduced moderately for a few days But even that reduction caused the prothrombin value to climb to 45%, so the dosage was increased again

Fig 6 shows the secondary rise of the prothrombin value which often takes place after the effect of the initial dose has ceased, when the subsequent dosage has been reduced too much Increased dosage on the sixth day brought the prothrombin value down to the therapeutic range, where it was kept fairly constant by continued slight adjustment of the dosage

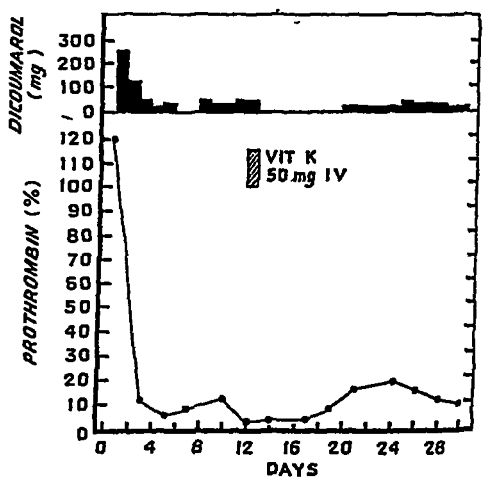

Fig 4—Adjustment of dosage of dicoumarol according to effect on prothrombin in a man, aged 75, with coronary thrombosis and very sensitive to dicoumarol

Fig 7 illustrates another phase A patient with myocardial infarction, who was at first moderately sensitive to dicoumarol had his prothrombin value kept down to about 10% with 50 mg of dicoumarol daily Thereafter his resistance to dicoumarol increased, and the maintenance dosage had to be more than doubled to produce the same effect At the time when small doses were sufficient to keep the prothrombin value down this patient was in a state of shock When he started to recover and his general condition improved, his resistance increased Such an increase of resistance is common in heart patients, especially those with myocardial infarction when their condition improves

Fig 8 shows how doses of dicoumarol should not be given The doses from day to day vary too much This is a very common mistake which is easily made when the dosage is based only on the current prothrombin value and not on the shape of the curve

It is clear from figs 2–8 that the dosage of dicoumarol must be based on the previous shape of the prothrombin curve A rise or a fall in the curve must at once be met by an increase or a decrease of the dosage The closer one approaches the ideal maintenance dosage for the patient, the smaller will be the variation in doses from day to day

A SURGICAL POLICY FOR PEPTIC ULCER

H. DAINTREE JOHNSON
M.B. Camb., F.R.C.S.
ASSISTANT SURGEON, ROYAL FREE HOSPITAL, LONDON;
CTURER IN SURGERY, POSTGRADUATE MEDICAL SCHOOL OF LONDON

I. M. ORR
O.B.E., M.D., Ch.M. Glasg., F.R.C.S.E.
SURGEON, ROYAL INFIRMARY, PRESTON;
RMERLY LECTURER IN SURGERY, POSTGRADUATE MEDICAL SCHOOL OF LONDON

The mortality of gastrectomy has fallen so satis- ctorily in recent years that this operation is no longer nned because of the risk it entails. Moreover, more d more physicians are recognising that only surgery n alter the course of the lifelong disorder from which ptic ulcers arise. At the same time, the great increase the number of gastrectomies, and particularly the ndency to make them subtotal, has caused concern out these patients' capacity to maintain health and ficiency on the diet obtainable in Britain today.

The aim of surgery must always be to discover and ctise the least interference that will adequately trol disease, imposing the smallest possible cost in e, function, and tissue. It was with this in mind that e set out, seven years ago, to ascertain whether the fer and less drastic operation of vagotomy might rove sufficient for the cure of peptic ulcer, and five ears have passed since we published our earliest xperience with it (Orr and Johnson 1947).

We remarked then that vagal resection might be ooked on as a reconnaissance in force in the war against eptic ulcer. Little is lost, we added, if on occasion it ails, for we still have at our disposal the full-scale attack y gastrectomy. A lasting success by vagotomy is a riumph of physiological strategy. A failure following gastrectomy, however, is an irretrievable reverse in which much has been sacrificed without hope of withdrawal.

By the time we next reported our results (Orr and Johnson 1949), though ground had been won and valuable information gained, we had been forced to resort to more comprehensive operations for most of our patients. The conclusion had become inescapable that, for permanent symptomatic relief, correction of the deformity and obstruction caused by scarring is at least s important as healing of the ulcer. We therefore ged that, for all ulcers which had become large and lous or had penetrated into adjacent organs, or where ajor hæmorrhage had taken place, gastrectomy should used, with or without the addition of vagal resection. Though, like most others, we abandoned vagotomy ne as a treatment for duodenal ulcer, we continued he follow-up on the patients who had been submitted to this operation, and we are thus able to analyse the results from four to seven years after.

LONG-TERM RESULTS OF VAGOTOMY ALONE

[illegible] original 108 patients submitted to vagotomy [illegible]duodenal ulcer in 1946–48 60% have received [illegible] and have declared themselves greatly [illegible] or since, 33% having been without even the [illegible] symptoms. However, 25% have had to [illegible]further surgery, either to relieve stenosis and [illegible] or to remove a recurrent ulcer, before a [illegible] achieved, 3 of the new ulcers being gastric ones. A further 15%, though they have not relapsed to the extent of requiring another operation, are only partially relieved of symptoms and have to have intermittent medical care. (81% of the original 108 patients now have *good* results, and the mortality has been nil.) In his survey of 736 patients submitted to vagotomy alone by many different surgeons, Pollock (1952) reported 44% of them as having unsatisfactory results and found evidence of ulcer relapse in 9·4%.

It was reported by St. John and Flood (1939), and many others have published similar figures, that after the successful medical cure of peptic ulcer 65% of patients have recurrent ulcers within two years. All our patients had long histories and recalcitrant symptoms and perhaps, on the average, had relatively advanced lesions. Hence it certainly cannot be said that vagotomy made little difference to their hitherto downhill progress, and there can be no doubt that the operation substantially alters the course of ulcer disease. Moreover, though 40% of patients *did not have sustained symptomatic relief* after this safe and modest manœuvre, only a few of those reoperated on had ulcers, most of them showing only *gross scarring and deformity* as the cause of their continued symptoms.

In the treatment of anastomotic ulcer following gastrectomy, there is still *an important place* for vagotomy; for a second gastric resection is a relatively dangerous undertaking. Moreover, a second gastrectomy has too often been followed by further ulcer recurrence. Again, for jejunal ulcer after earlier gastro-enterostomy, vagotomy is sometimes the wisest choice when the patient, as is so often the case, is a poor surgical risk.

Even in the absence of obstruction, vagal resection usually causes retention of food in the stomach; and though this contributes to the cure of duodenal ulcer, it may give rise to untoward symptoms. Fortunately this retention does not occur when a well-designed drainage operation has been added to vagotomy.

VAGOTOMY PLUS GASTRO-ENTEROSTOMY

Neither vagotomy nor gastro-enterostomy alone can be depended on to cure and control ulcer disease with sufficient regularity; but, when the two operations are done together, the results are said to have been excellent. Crile and his colleagues (1952) have used this combination well over 400 times for duodenal ulcer, and report only 6% recurrences and less than ½% deaths. This is surely preferable to less than 1% recurrences but 4% deaths, such as may be expected with radical gastrectomy.

We have used vagotomy in 12 cases of anastomotic ulcer after earlier gastro-enterostomy, and in 2 of our early patients who had had vagotomy alone gastro-enterostomy was added later. In 26 cases of duodenal ulcer we have used vagotomy and gastro-enterostomy together. Such small numbers can give no very weighty support to Crile's claims, but the results have been very satisfactory, and we are bound to keep an open mind about this operation. Pollock (1952) has collected and followed up 462 cases after vagotomy and gastro-enterostomy by a number of different surgeons and has found only 8% of clinical failures among them.

It has so far been our policy to reserve vagotomy and gastro-enterostomy for a few patients in whom, because of obesity and emphysema, for example, gastrectomy might have been unduly difficult and hazardous.

SUBTOTAL GASTRIC RESECTION

A radical gastrectomy is the operation perhaps most widely favoured in Britain at present and we have used it extensively ourselves.

Visick (1948) defined subtotal gastrectomy as one which removes the first part of the duodenum, the pylorus, the whole of the lesser curvature, and the greater curve up to, but not including, the *uppermost* of the short gastric vessels. Done in this way gastrectomy leaves a very small gastric pouch indeed, with few tional doses of only 2–4 mg a day, the same result would be *obtained* The figure proves, better than words, the dependability and exactness of Owren's *method* of prothrombin estimation when done by trained personnel

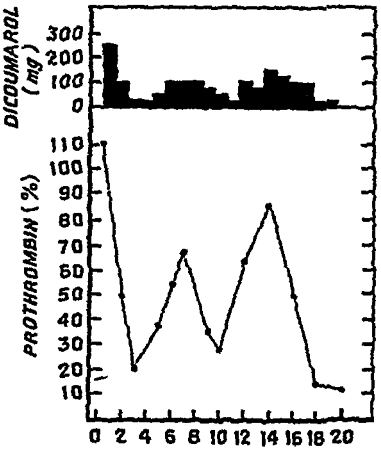

Fig 8—Wrong way of adjusting dosage of dicoumarol—on current prothrombin value instead of previous shape of prothrombin *curve*—in a man, aged 69, with phlebitis

The long interval between each estimation of the prothrombin value makes it necessary to be very cautious One rarely has to make any great change in dosage because of the patient's tolerance having increased or decreased, but it will sometimes be desirable or necessary to have an extra estimation made, especially if the prothrombin value has decreased too much As a rule one estimation a week will even then be sufficient

The adjustment of dosage in ambulant outpatients with infrequent estimations of the prothrombin value is much more a matter of experience than in the treatment of inpatients It can only be learnt by trial and error It is essential to have a diagram with a constant scale for showing the variations in prothrombin values in relation to time intervals, so as to assess the effect of a change in dosage It is also of the utmost importance to make sure that patients really take the dose prescribed for them even the most intelligent patient can be forgetful I have therefore made it a rule that each patient receives a written dosage schedule, covering each day of the period between two estimations of prothrombin After taking each day's dose the patient is required to cross off the dose If he forgets to take his daily dose, the fact will be shown on his schedule and will be noticed Unfortunate consequences can then be avoided By taking these precautions effective treatment can be given to nearly all ambulant patients without incurring any risk

Experience has further shown that it is difficult to achieve a stable maintenance dosage and an even prothrombin curve in heart-failure This is probably caused by variations in the degree of congestion in the liver, involving variations in the synthesis of prothrombin, and leading to fluctuations in tolerance of dicoumarol

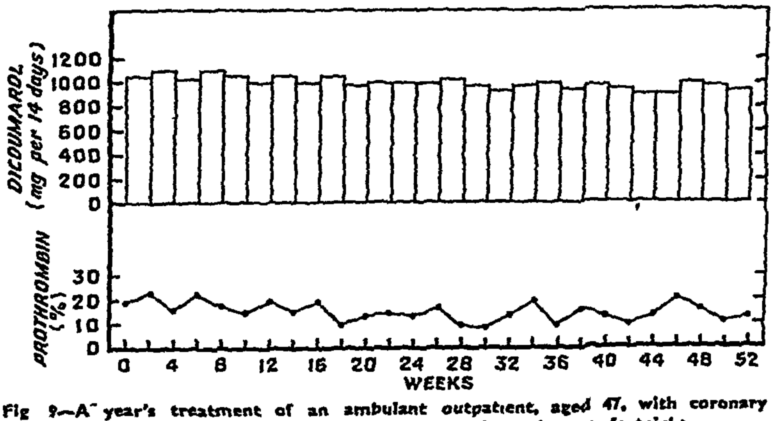

Fig 9—A year's treatment of an ambulant *outpatient*, aged 47, with coronary thrombosis the prothrombin value being estimated every fortnight

It is a good rule to make patients aware of the dan of hæmorrhages, and to advise them to report to th physician immediately if they should observe hæmatu epistaxis, blood in the stools, or ecchymoses in the s and mucosæ without traumatic cause

The *only* complication of any importance fr dicoumarol treatment is hæmorrhage, and it is r when one uses a dependable method for the estin tion of prothrombin and administers the dicouma according to the above-mentioned principles In hospital treatment of 522 patients in Oslo Munic Hospital not a single serious hæmorrhage was observ Slight hæmorrhages, such as hæmaturia, epista bleeding hæmorrhoids, and streaks of blood in the sputu all of short duration, were seen in 8 patients In one these patients (bleeding hæmorrhoids) the hæmorrh was thought serious enough to need a blood-transfusi particularly as the patient had recently had coron thrombosis In the 7 other cases it was sufficient to g vitamin K intravenously and to withhold dicoumarol fo while Among 107 ambulant patients treated for perio varying between one and twenty-six months no serio hæmorrhage was observed One patient had an epista which required tamponage Another, a man aged 70, h a muscular hæmatoma in the right thigh after a long wa In the epistaxis case the prothrombin value had remain low (8–9%) for a fortnight before the hæmorrhage to place In the hæmatoma case the prothrombin val was 15%, and possibly a slight traumatic episo was partly responsible Both patients have sin continued to receive dicoumarol treatment witho complication

Vomiting can sometimes be a hindrance in admin tering the initial dose, particularly where patients fe nauseated and vomit before receiving treatment, as often the case in coronary thrombosis In such instanc it is advisable not to administer the whole initial do (10 tablets) at once but to give it in smaller portio during the day.

From what has been said above it is evident that o cannot schematically specify a universal dosage dicoumarol, even where patients have the same pr thrombin value The dicoumarol dosage must vary fro one patient to another according to the shape of t prothrombin curve The only dosage which can universal is the initial dosage, by which is meant t first and second days' doses The advantage of this h been stated above but is worth repeating it takes som time from the administration of the initial dose unt full therapeutic effect is achieved The longest time required in resistant patients, in whom the given initi doses are too small to decrease the prothrombin val to the therapeutic range Continued heavy doses duri the following days may be necessary (see fig 5) Despi this, a substantial number of days can often pass befo one achieves full therapeutic effect Out regard to sensitive patients it would inadvisable to increase the size of the initi dosage much beyond that mentioned abov In all cases where one wishes to obtain th quickest possible effect one ought to beg treatment with heparin and dicoumar together The heparin treatment mu then be continued until the prothromb value has reached the therapeutic range

The indications and contra indication of dicoumarol treatment in differen thrombo embolic *conditions* will not b discussed here They have been extensivel treated by other workers (for referenc see Marple and Wright 1950), nor ar the results of treatment in differen thrombo embolic conditions considere here

36 of them with vagotomy added), 26 had vagotomy us gastro-enterostomy, 2 had short-circuits for stenosis ter earlier vagotomy, and 12 had vagotomy alone for nastomotic ulcers after earlier gastro-enterostomy.

There were 6 postoperative deaths, a mortality of 1% for the policy as a whole or 1·2% for the 486 astrectomies. The causes of death were: coronary rombosis; burst abdomen followed by general eritonitis; uræmia in an elderly man with prostatic bstruction; septic thrombophlebitis starting in a vein sed for blood-transfusion; general peritonitis developing fter discharge from hospital after an apparently neventful convalescence; and suppurative cholecystitis a patient known to have gall-stones, which were, erhaps unwisely, not dealt with at the same time as the astrectomy. Since the end of the review period we ave performed a further 114 operations with 3 deaths lose together. Our mortality has therefore risen to 1·4% or 640 cases.

METHOD OF FOLLOW-UP

Though nearly all the patients included in this review vere interviewed by one or other of us at regular intervals, ve have come to the conclusion that a carefully composed questionnaire yields data more susceptible to bjective analysis and allowing comparisons of greater alidity than can be gained in conversation; for at nterviews not only do questions vary in the way they re put to the patient, but also his answers are likely o be influenced by the knowledge that he is, or is not, n the presence of the surgeon who did his operation. Our analysis has therefore been made on the basis of written questions to each of which alternative answers re offered—e.g., "Have you, since your operation, uffered from wind pain? YES, OCCASIONALLY OR SLIGHTLY, NO. Did you have wind pain as distinct from lcer pain before your operation? YES, OCCASIONALLY OR SLIGHTLY, NO. If so, is it now BETTER, THE SAME, WORSE? (Cross out two answers in each case.)"

After questions about ulcer pain, wind pain, vomiting of food, regurgitation of bile, heartburn, diarrhœa, attacks of weakness, giddiness, sweating, &c., size of meal taken without discomfort, and progress in body-weight, the patients are asked: "Do you find that, since your operation you are, all things considered, 1, CURED AND NORMAL; 2, MUCH BETTER; 3, A LITTLE BETTER; 4, NO BETTER; or 5, WORSE? (Strike out four of the alternatives and write nothing in.)"

Patients seem to have no difficulty in deciding whether to put themselves in category 5 or 4 or 3, but the choice between 2 and 1 caused some indecision. The more cautious were afraid, after years of relapse before operation, to pronounce themselves permanently cured, even though free from symptoms so far. We should have done better to call these two categories NORMAL AND APPARENTLY CURED and MUCH BETTER BUT NOT NORMAL. Possibly in the large groups dealt with psychological factors have evened out.

TABLE I—CATEGORIES SELECTED BY PATIENTS IN ANSWER TO THE QUESTION: "TAKING EVERYTHING INTO CONSIDERATION, DO YOU FIND YOURSELF, SINCE YOUR OPERATION, 1, CURED AND NORMAL; 2, MUCH BETTER; 3, A LITTLE BETTER; 4, NO BETTER; or 5, WORSE?"

Category	1	2	3	4	5	1 or 2	3, 4, or 5
	Percentages						
All lesions:							
Radical gastrectomy (222) ..	42	47	9	1·8	0·5	89	11
Policy group (513)	53	42	4	0·4	0·8	95	5
Duodenal ulcer:							
Radical gastrectomy (125) ..	46	41	10	1·6	0·8	87	13
Policy group (353)	54	41	4	0·6	0·8	95	5
Gastric ulcer:							
Radical gastrectomy (75) ..	36	56	7	1·3	0	92	8
Policy group (105)	49	47	3	0	1	96	4
	Not percentages						
Anastomotic ulcer:							
Radical gastrectomy (9) ..	5	4	0	0	0	9	0
Policy group (25)	13	10	2	0	0	23	2

Patients who could not be followed up fall into two groups: (1) those who will not coöperate, either because they are well and cannot be bothered or because they have done badly and are dissatisfied and resentful; and (2) those who have left the district for an unknown address and are not reached by follow-up communications. By persistence and personal visits we eliminated the first group, but were left with 7 in the second and have had to omit them from our calculations. Of 4 patients who died during follow-up, from causes unrelated to ulcer, the results for 3 have been included up to the date of the last review; but the 4th died within a few months, of carcinoma of the bronchus, and is excluded.

All these figures refer to the policy group. In the high-gastrectomy group we were rather less successful, for 15 patients remained untraced. 7 others died, 4 of causes unrelated to ulcer and 3 of unknown causes. 4 of these had not been followed for long enough before death to be included. We were thus left with 222 satisfactory follow-ups for analysis in this group out of 241 survivals.

ULCER RECURRENCE

No proven recurrent ulcer has yet appeared in the "policy" series; but there are 4 patients (0·8%) whose symptoms have never been relieved by their operations. In the high-gastrectomy group 2 proven recurrent ulcers developed and 3 other patients did not get relief from their symptoms from the start (2·2% in all). We may therefore claim that there is as yet no very significant difference in success, as regards control of ulcer disease, between routine radical gastrectomy and the selection policy.

SIDE-EFFECTS AND SATISFACTION WITH RESULTS

The clinical failures of gastric surgery are nowadays far more often due to the side-effects of operation than to ulcer relapse. The incidences of the various symptoms remaining, or appearing for the first time, after operations

Sl., occasional or slight. L, large. M, medium. S., small.

The hydatid complement fixation test and the intradermal test have both been employed for more than forty years to assist in the diagnosis of hydatid disease While the usefulness of the two tests has been generally acknowledged, and one or other or both much used in other countries, there is little in the literature to show that, outside Australia, the careful work of Hamilton Fairley (1922) is fully appreciated Certainly in this country, as far as can be ascertained, the importance of using standard reagents does not seem to be generally accepted

This communication is intended to redirect attention to the need for standardisation of the reagents for both the hydatid complement-fixation and the intradermal tests and to demonstrate their enhanced value (admittedly in a small number of cases) in primary diagnosis, when an accurate " standardised " technique is followed

COMPLEMENT-FIXATION REACTION

Bordet and Gengou (1901) showed that when a suspension of *Pasteurella pestis* reacted with a plague antiserum in the presence of complement there was complete fixation of this latter substance This complement-fixation reaction was first known as the Bordet-Gengou phenomenon Further experiments demonstrated the specificity of the reaction and that other bacterial antigens and their homologous antisera fix complement in the same way The specificity was rated very high and the test was employed by Bordet and Gengou in 1906 as the final proof of the authenticity of *Hæmophilus pertussis* (Bordet Gengou bacillus) as the causal agent of whooping cough

Later observations by Gengou (1902) showed that the sera of animals immunised with dissolved protein, when brought together with their specific antigens, likewise formed combinations which fixed complement, and this led to a much wider application of the test During the same year that Wassermann, Neisser, and Bruck (1906) produced their classical paper on the serological diagnosis of syphilis, the application of the Bordet-Gengou phenomenon to the diagnosis of hydatid disease was described by Ghedini (1906) The most important of the early studies were, however, undertaken by Weinberg (Weinberg and Parvu 1908, Weinberg 1909), and today the hydatid complement-fixation test is frequently referred to as the Ghedini-Weinberg reaction Although there are several references in the literature to the varying fixing powers of the different hydatid fluids as antigens—particularly by Sonntag (1913)—opinions differ widely about this variation It was not until Hamilton Fairley (1922) showed that the specific antigen in a hydatid fluid was derived from the developing embryo, and that the potency of an antigen was related to the number of scolices present in the cyst from which the antigen was prepared, that any progress was made towards standardisation of the test Relying on this method of assessment, Fairley found that fluids rich in scolices regularly proved to be good antigens for the complement-fixation test Pooled fluids of this sort from several cysts, handled with aseptic precautions, give very consistent results Fairley preferred to use the clear supernatant from fairly fresh fluids without filtration or the addition of preservative

Although the use of fresh sheep hydatid fluid is feasible in areas where the disease is endemic and sheep infestation heavy, it cannot be relied on in this country where hydatid cysts are not commonly found in sheep Dried extracts of scolices have proved satisfactory, but there are always difficulties in using dried antigens for quantitative complement fixation work, where the batches of sera to be examined at any one time are relatively small A number of workers in the past used phenol as a preservative for the fluid hydatid antigen, but there is little reliable information about the keeping properties of such material Hamilton Fairley (1922) reported his preference for unpreserved antigens, but other workers have found merthiolate 1 in 10,000 to be satisfactory

Experience had shown us that the complement fixing antibody-titre of human sera from patients suffering from hydatid disease remain unaltered over very long periods provided they are sterile and maintained at +4°C It was decided therefore to attempt to standardise the test by employing a standard serum to titrate hydatid antigens and to repeat these tests at regular intervals to assess their stability over long periods It was also decided to investigate the possibility of immunising suitable animals for the production of a standard serum instead of having to rely on the chance availability of satisfactory human serum We were fortunate enough to obtain a fair amount of human serum from a case of hydatid disease which possessed strong complement fixing properties, this was adopted as the provisional standard serum, and through the kindness of Dr Hilda Gardner, of the Royal Melbourne Hospital, we received a generous supply of a very good sheep antigen preserved with 1 in 10,000 merthiolate

Preliminary tests showed that this antigen in the undiluted state did not by itself fix complement, and that its optimum dilution for the test was 1 in 4 when the provisional standard gave complete fixation of complement up to a dilution of 1 in 64

The technique adopted and maintained unchanged since was as follows

All reagents were used in unit volumes of 0 25 ml All sera including standard, negative controls, and test specimens were inactivated and set out in doubling dilutions from 1 in 2 to 1 in 128 Antigen, diluted 1 in 4, and $2^1/_2$ doses of complement, were added successively to each tube After thorough mixing, fixation was allowed to proceed for eighteen hours at +4°C After standing at room temperature for one hour the hæmolytic system (5% washed sheep cells plus 5 doses of hæmolytic amboceptor) was added *The racks were incubated* at 37°C for thirty minutes and preliminary readings were taken The racks were returned to the refrigerator before the final readings on the degree of hæmolysis were recorded

Notation		
	Complete fixation	+ + +
	75%	+ +
	50%	+
	25%	±

An arbitrary standard was thus set up for the hydatid complement fixation test, both for the technique itself and the reagents employed in the test It was decided that the serum should be the standardising agent and that no antigen should be used which when diluted 1 in 4 for the test did not give full fixation of complement with the standard serum at a dilution previously determined, and which did not in undiluted form by itself fix complement or react with sera from patients not suffering from hydatid disease

It is now almost two years since we adopted this technique and over this period batches of patients' sera have been examined at approximately fortnightly intervals In these tests the standard serum has always been included as a check on the potency of the antigen employed The original antigen has been used throughout the series reported, but a number of other satisfactory antigens have been used in parallel with it as additional controls

Our previous experience regarding the stability of the complement-fixing antibodies in human sera stored at +4°C over long periods has been confirmed The titre of a number of positive sera have now been tested at intervals over a year under controlled conditions and have been found to be unchanged

Other workers have explored the possibility of immunising animals for the preparation of hydatid complement gastrectomy with vagotomy and those of five-sixths gastrectomy alone.

The experiments on animals upon which Dragstedt 1945) based his use of vagotomy in man seem indeed to point in the right direction. It is not on these, however, nor on biochemical theory that the status of the operation must rest, but upon the clinical results.

We believe that vagotomy, including division of selected branches, though it is of strictly limited application, has now established for itself an important ancillary rôle in the surgery of peptic ulcer in intensely hypersecreting people. Moderate or two-thirds gastric resection alone is adequate to prevent recurrence of ulcer in patients with normal or low secretion-rates but sometimes fails in those with gross oversecretion. The addition of vagotomy makes moderate resection a satisfactory operation in these hypersecreting patients as well. The effect of this combination on gastric secretion is not significantly different from that of radical, five-sixths, or seven-eighths gastrectomy alone, but its power to prevent recurrence appears to be at least as good and its symptomatic results significantly better.

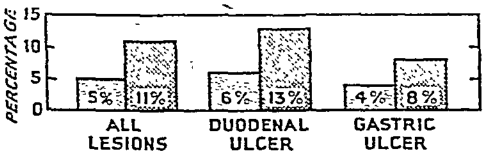

Fig 2.—Failures: percentages of patients selecting categories 3–5.

SUMMARY

The long-term results in 108 patients with duodenal ulcers submitted to vagotomy alone from four to seven years ago are reported. 60% of them continue to have good results, but the operation cannot be recommended, because, unless the effects of scarring and deformity are overcome at the same time, sustained symptomatic relief cannot be depended on.

However, vagus resection has proved and maintained its efficiency in controlling excessive acid secretion and therefore continues to have an important ancillary rôle in ulcer surgery.

During the past five years we have followed a policy for peptic ulcer in which patients are selected, according to the results of special investigations of acid secretion, either for two-thirds gastric resection alone or for a similar moderate gastrectomy with the addition of vagotomy. Gastro-enterostomy plus vagotomy has been used for a few bad-risk patients.

A method of follow-up and assessment has been used in which the patients themselves assess their results and the bias of the observer is eliminated.

The results of our policy, ascertained in this way in 526 cases, are compared with those of 241 radical (from four-fifths to seven-eighths) gastric resections used for similar lesions during the same period and similarly assessed (figs. 1 and 2).

Though both methods of treatment have achieved a high order of success, the "policy group" has shown a lower incidence of every side-effect and a higher proportion of satisfactory results during the period reviewed. The mortality in the policy group was 1·1%.

THE SERUM ANTIBODY RESPONSE IN ALASTRIM

K. McCarthy
M.D. Lpool
LECTURER IN BACTERIOLOGY

A. W. Downie
M.D., D.Sc. Aberd.
PROFESSOR OF BACTERIOLOGY

UNIVERSITY OF LIVERPOOL

In the outbreak of alastrim in the Rochdale district of Lancashire in the spring of 1952 there were more than 150 cases. Many of the patients, particularly in the earlier weeks of the outbreak, had not been vaccinated; and these cases offered an opportunity to investigate the antibody response to the infection. From 19 unvaccinated patients 21 sera were obtained and examined with three objectives: (1) to compare various laboratory methods for detecting antibody; (2) to ascertain the time of appearance of antibody in relation to onset of symptoms; and (3) to assess the specificity of the antibody response.

In patients suffering from alastrim or smallpox who have never been vaccinated the estimation of antibody in the serum may be a useful diagnostic procedure. In the Rochdale outbreak it was so used to make a retrospective diagnosis in patients who had recovered and for whom other laboratory diagnostic techniques could not be used. For the detection of antibody the complement-fixation test has been commonly employed: the serum is tested against an antigen prepared from smallpox or alastrim crusts, from vaccinia-infected tissue from rabbits or from egg membranes infected with vaccinia, variola, or alastrim viruses (Downie and Macdonald 1950). The test for antihæmagglutinins has become popular of recent years and has been used for the estimation of antibody in the serum after vaccination (Nagler 1944) as well as in cases of smallpox (Collier et al. 1950). The neutralisation test, made by injecting a mixture of virus and patient's serum into the skin of rabbits or on the chorio-allantoic membrane of chick embryos, also gives satisfactory results (Loutit and McClean 1945, Blattner et al. 1943). We used all these three methods in examining each of our 21 sera.

Previous work from this and other laboratories had shown the close serological relation between the viruses of variola, vaccinia, alastrim, and cowpox, using sera from immune animals. The sera from some of the alastrim patients were therefore tested against these viruses to find out whether the response to infection in man was more specific than that of experimental animals. Obviously the results might have some bearing on the value of laboratory tests in the differential diagnosis of alastrim, smallpox, and generalised vaccinia.

MATERIALS AND METHODS

Sera

All sera were stored in the refrigerator at about 4°C. Before use they were inactivated by heating at 57°–58°C for twenty minutes.

Viruses

One strain of each of alastrim, smallpox, vaccinia, and cowpox viruses was used. The alastrim strain was recovered

TABLE V—RESULTS OF SERIAL TESTS IN THREE PATIENTS AFTER REMOVAL OF CYSTS

Clinical condition	Date	Complement fixation result in serum dilutions							Remarks
		2	4	8	16	32	64	128	
Liver and lung	1945	Strong positive titre unknown							Cyst removed from liver
	Dec 5 1950	+	±	−	−	−	−	−	Casoni ± ? recurrence
	Feb 12, 1952	+++	+++	+++	+	−	−	−	Definite recurrence Cyst found in l Casoni ++
Liver	June, 1951	+++	+++	+++	+++	+++	++	±	Operated on, May 1951
	Feb 1952	+++	+++	++	+	+	−	−	No symptoms Casoni +
	Sept, 1952	+++	++	+	−	−	−	−	No signs or symptoms
Liver	Dec 5 1950	+++	+++	++	±	−	−	−	Cyst removed
	Feb 13 1952	−	−	−	−	−	−	−	No symptoms or signs

These have been omitted from the table because the fluid itself had not been examined for scolices and antigenicity, and the blood-serum had not been examined for complement-fixing antibodies

Of 49 patients examined for diagnosis before any exploratory needling or operation, 20 were found to have negative skin reactions and hydatid complement-fixing antibodies could not be demonstrated All these patients were found to be suffering from a condition which was definitely not hydatid disease The remaining 29 were proved by operation to have hydatid cysts, but whereas 27 (93%) gave positive complement-fixing reactions only 25 (86%) gave positive skin reactions

A primary uncomplicated cyst of the liver may contain a fluid very rich in scolices but there may be little leakage into the circulation with only moderate serological reactions Table III shows the results in such a case On the other hand a patient who had a cyst removed one year previously and was then operated on again for removal of a further cyst gave a type of reaction which may be the result of escape of antigen at first operation plus the effect of the new cyst developing (table IV)

TABLE IV—RESULTS OF TEST IN PATIENT WITH HYDATID CYST WHO HAD HAD ANOTHER CYST REMOVED A YEAR PREVIOUSLY

Antigen	Serum	C F T result
Standard	Standard	1 in 64
Standard	Patient's	1 in 64
Patient's	Standard	1 in 8

Skin test strong positive

Table V below illustrates the results of serial tests performed on these patients after operation for removal of hydatid cysts, one of which shows a fall in complement-fixing antibodies followed by a rise as a new cyst developed The other two cases of single cysts of the liver with no evidence at present of any new cyst development show continuous falling titres

DISCUSSION

Since Hamilton Fairley (1922) showed that the antigen content of a hydatid fluid depended on the presence of scolices, it has been obvious that a sterile cyst will not contain antigen and that serological reactions will not be positive in patients with cysts that do not contain scolices Information about the frequency of sterile cysts is meagre, but they cannot be very common in man

In only 1 case in the present series was a human fluid found to be completely devoid of antigen, although several appeared to have very little Scolices are not always to be seen in fluids submitted for examination, because only the clear supernatant may be sent In the past, before we adopted standard reagents and technique, it was not always possible to assess the value of negative complement fixation and intradermal tests The present series is small, but there was only the 1 case with negative serological reactions in which the evidence at operation showed that the patient was suffering from a hyda cyst In this small series chance may have played a p in determining the favourable results, but there was selection of cases beyond the exclusion of those wh complete investigations, including the actual demonst tion of the presence or absence of a hydatid cyst, had been carried out In no case in which the final diagno was not hydatid disease was the skin test or the comp ment-fixation reaction found to be positive Th results compare very favourably with previously record results, but, apart from the series recorded by Fairley a Kellaway (1933), there was little information about t potency or supply of the reagents used The Austral workers found the intradermal test to be somew more sensitive than the complement-fixation test, figures, in which the reverse was found, cannot regarded as significant in view of our small numb The actual titration of complement-fixing antibody the patients' serum with standardised reagents, now t their stability has been demonstrated, appears to us have advantages which may extend the value of the t beyond the diagnosis of the primary cyst Some evide is presented to show that after the excision of the prim cyst the complement-fixing titre tends to fall slowly will rise again if further cysts develop It is obvious t additional experience is required before this sugge is accepted without reserve as having value in progno

SUMMARY

A technique employing accurately standard reagents for the serological diagnosis of hydatid dise is described

In a series of 49 cases where the exact diagnosis made at surgical operations, 20 non-hydatid cases g negative complement-fixation and intradermal reactio and 28 of the 29 proved cases gave positive serolog reactions with a slight advantage to the compleme fixation test (27 positive complement fixation test 25 positive Casoni)

We have to thank Dr Naomi Datta for help in the prep tion of the provisional standard sera We are also grat to the doctors who have sent us detailed reports on t cases, and particularly to Dr G Wetherley Mein for careful measurements of skin reactions

is of doubtful significance, and less than 30% is within the range of fluctuation about the mean shown by serum-virus mixtures containing replicate samples of the same serum. Serum no. 3 we would therefore regard as negative and serum 1 as a doubtful positive in the neutralisation test. It would appear from these results that neutralising antibody is the earliest to appear and that this, though perhaps varying in different patients, may be detectable as early as the fifth day after the onset of symptoms. Similar findings have been obtained in this laboratory with a larger number of smallpox sera (results to be published). Although no sera from these alastrim cases were obtained more than forty-three days after the onset of illness, our tests on smallpox sera have shown that neutralising antibody can be found years after an attack at a time when antihæmagglutinin and complement-fixing antibody can no longer be detected. The present findings confirm our previous experience that the order of reliability of these techniques for antibody estimation is neutralisation>antihæmagglutinin>complement-fixation. It may be noted that in the examination of smallpox and post-vaccination sera Collier et al. (1950) obtained higher titres of antihæmagglutinin than those shown in table I. The apparent difference is exaggerated by their method of calculating titres (in terms of the dilution of serum in the total volume of fluid per tube). Had we adopted this method, the titres recorded in this paper would have been increased threefold. Their hæmagglutinin was an extract of "smallpox lymph" prepared in buffaloes and may well have been a more sensitive indicator than our extracts prepared from infected chorioallantois.

Specificity of the Antibody Response

The investigations on this point were made with the complement-fixation and neutralisation techniques. The difficulty of obtaining active hæmagglutinins from alastrim, variola, and cowpox material precluded the use of antihæmagglutination titrations for assessing specificity of antibody.

Complement-fixation.—In these tests infected chorio-[illegible] mbranes were used for the preparation of [illegible] :ause this was the only tissue which could [illegible] be used as a source of antigen for all four viruses. The results of tests with 13 of the alastrim sera are shown in table II. There is little evidence of selective reactivity of the sera with the alastrim antigen. The slightly higher titres obtained with the variola and cowpox antigens are to be attributed to the greater reactivity of these two preparations. Likewise, complement-fixation tests with human sera obtained after vaccination or after recovery from smallpox or cowpox showed a similar lack of specificity. It has been suggested (MacCallum 1952) that with human convalescent sera chloroform-extracted egg antigens give complement-fixation reactions sufficiently specific to differentiate the antibodies resulting from smallpox and cowpox infections. Table III shows the results of tests with egg antigens that had been extracted overnight with chloroform to make 20% by volume. There is here also little evidence of specificity, except perhaps with the cowpox serum, which reacted to slightly higher titre with the homologous antigen; and this antigen gave, on the whole, lower titres with the variola and alastrim sera than did their homologous antigens. The differences, however, were slight and not in our opinion sufficiently great to make the use of this type of antigen of differential diagnostic value in the examination of convalescent sera from patients infected with those viruses.

TABLE IV—NEUTRALISATION OF ALASTRIM, VARIOLA, VACCINIA, AND COWPOX VIRUSES BY CONVALESCENT SERUM (CASE NO. 17)

Serum dilutions	Per cent. virus surviving (derived from pock counts)			
	Alastrim	Variola	Vaccinia	Cowpox
1/5	1	9	20	13
1/50	87	82*	90	120*
1/500	115	85	87	95
Control serum 1/5 ..	100	100	100	100

*These figures fall within the range of variation with normal serum-virus mixtures.

Neutralisation tests.—With immune sera prepared in animals, neutralisation tests with undiluted sera had not served to differentiate viruses of the pox group (McCarthy and Downie 1948). However, when the sera were tested in dilutions, higher neutralisation titres were usually obtained against the homologous virus (Downie and McCarthy 1950). The serum from one of the alastrim patients was therefore tested in tenfold dilutions against the four viruses, a normal human serum being used as control. The figures in table IV record the percentage of surviving virus as compared with the control and not the percentage neutralisation as in table I. There is significant neutralisation of all the viruses by 1/5 serum dilution but none with serum dilutions of 1/50 or 1/500. It is doubtful if the differences in the percentages of surviving virus with the 1/5 dilution of serum are significant; for it has been our experience that post-vaccination sera usually show better neutralisation of variola than of vaccinia virus, and in our previous experimental studies alastrim virus appeared to be more readily neutralised than other pock viruses by heterologous and homologous immune sera (McCarthy and Downie 1948, tables I and II).

DISCUSSION

Of the techniques used in the examination of the sera from alastrim patients, the neutralisation test was the more sensitive in that antibody was found in earlier specimens of serum which were negative by the complement-fixation test. It is to be noted, however, that in the neutralisation tests the serum was used in a dilution of 1 in 2, whereas 1 in 5 was the lowest dilution tested by complement-fixation. It seems likely that the fall in temperature and improvement in the patient's condition which occurs about the fourth or fifth day of illness is related to the production of antibody (Downie 1951), and by the neutralisation technique antibody may be found in the blood very soon after clinical improvement occurs. Such antibody is presumably the excess over that fixed by virus antigen in the tissues and body-fluids. For diagnostic purposes, however, the neutralisation test is not so conveniently carried out as is the complement-fixation test. The test for antihæmagglutinins, which is certainly as sensitive as complement-fixation, requires freshly prepared hæmagglutinin, because this antigen deteriorates within a few weeks at ordinary refrigerator temperature. On the other hand complement-fixing antigen may be kept under similar conditions for years without deterioration. Moreover, as complement-fixing antibody usually disappears within a year after vaccination, the complement-fixation test is a useful diagnostic procedure in suspected cases of smallpox who have been vaccinated more than twelve months previbeen jaundiced For some five years he had had nasal catarrh and cough, productive of a small amount of greenish sputum, and in July, 1948, these conditions had worsened About the same time he began to suffer from conjunctivitis In November, 1948, cutaneous pigmentation was noticed by the patient, first on his trunk and later down his thighs midway to his knees In December, 1948, his voice became husky and he felt generally but vaguely unwell

On examination he was found to have scattered lesions of dermatitis herpetiformis, some of which were infected In addition he had a "raindrop" type of brownish pigmentation of his trunk and upper thighs There was hyperkeratosis of his palms which may in part have been occupational His liver was enlarged to one hand's breadth below the costal margin (fig 1) and was hard but not tender There was no abnormality in the cardiovascular, respiratory, or central nervous systems and no evidence of peripheral neuritis

Investigations—He was admitted to hospital on April 4, 1949, and investigations gave the following results serum-bilirubin 0 95 mg per 100 ml , alkaline phosphatase 7 9 units, thymol turbidity 5 units, serum proteins 7 4 g per 100 ml (albumin 3 6 g , globulin 3 8 g), prothrombin concentration 90%, blood-urea 40 mg per 100 ml , urea-clearance 105% of the average normal function Radiography of the chest showed no abnormality

Treatment and Its Results—He was given a high-protein diet with vitamin supplements and there was a gradual reduction in the size of the liver, which ceased when it was three fingers breadth below the costal margin

As excretion of that part of a dose of inorganic arsenic which does not enter into combination in the tissues is complete in ten to fourteen days (Taylor 1948), the urinary arsenic excretion was not estimated until arsenic had been withheld for three weeks The excretion was then estimated by Mr Harri Heap, Manchester city analyst, and the amount of arsenic in each of 6 twenty four hour specimens was found to be within normal limits This having been ascertained, a course of dimercaprol was commenced in an attempt to free the combined arsenic Intramuscular injections of 3 mg per kg body-weight were given four hourly for forty eight hours and then twice daily It will be seen from fig 2 that the urinary excretion of arsenic increased considerably The injections were continued until, after seventeen days, there was no further significant excretion

No toxic effects were caused by the dimercaprol, but the patient had some pain at the injection sites During treatment there was a return of his sense of well being and the liver edge receded to one finger's breadth below the costal margin

Multiple puncture vaccination with calf lymph was performed for the dermatitis herpetiformis (Cecil 1947) and a good primary take was obtained A few days after vaccination the skin lesions cleared

On discharge the patient felt well enough to open a business of his own When last seen on Sept 20, 1950, he had remained well The dermatitis herpetiformis had returned soon after discharge, but the lesions had been few and scattered and much less than when the condition was under treatment with arsenic There had been no change in the hyperkeratosis of the palms or in the pigmentation of the skin The liver edge had now reached the costal margin but remained easily palpable and the liver surface was quite hard and apparently smooth On his last attendance the th turbidity was 4 units whilst the plasma proteins to 8 98 g per 100 ml with fibrinogen 0 44 g , albumin 4 3 and globulin 4 24 g.

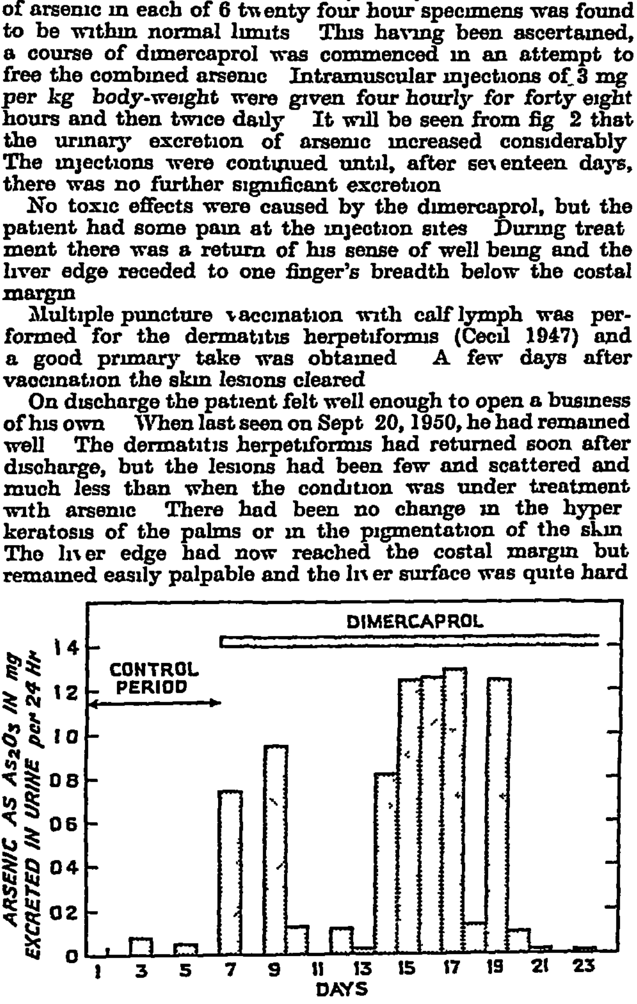

Fig 2—Urinary arsenic excretion before and during administration of dimercaprol

DISCUSSION

Inorganic arsenic, after absorption, passes to the l where a considerable proportion is stored , the rema reaches the general circulation, and that part w does not become fixed in the tissues is excreted, al entirely by the kidneys, in ten to fourteen days retained arsenic has attached itself to SH- contai protein components of the pyruvate oxidase sys The high toxicity of trivalent arsenicals is due to t ability to form stable arsenical-ring compounds such proteins (Eagle et al 1946) Thus arsenic by poisoning the function of cells, not their struct

Dimercaprol was discovered as a result of work car out on the thesis that simple dithiol compounds m form relatively stable ring compounds with triva arsenicals and consequently might compete effectively arsenic with dithiol tissue proteins This thesis first proposed by Stocken and Thompson and t work is referred to by Peters (1948) In prac dimercaprol has been found not only to combine w free arsenic but also to remove arsenic from it combination (Eagle et al 1946, Carleton and Peters 19 The latter reaction may be represented as

Tissue protein arsenic + dimercaprol → dimercaprol t arsenite + tissue protein

It is of this latter property that we have taken advant in treating our patient It should be noted, howe that cell damage may be irreversible even if the ars be removed (Taylor 1948)

We believe this to be the first report of the u dimercaprol in toxipathic hepatitis due to chr inorganic arsenic poisoning In the absence of a hist of jaundice or of other factors liable to cause hepat we do not feel that the toxipathic hepatitis in our pati can be dissociated from his ingestion of arsenic

The urinary excretion of arsenic had been wit normal limits before treatment , yet when the pati was given dimercaprol he excreted considerable amou of arsenic in the urine This confirms previous obser tions that dimercaprol can remove arsenic from combi tion with tissue proteins There is some evidence t the arsenic removed by dimercaprol is that part whic causing most damage (Carleton and Peters 1946), and reasonable to suppose that the arsenic removed fr our patient was interfering with his pyruvate oxidat system The liver is, of course, intimately concer with carbohydrate metabolism, and this may expl the high storage-rate of arsenic in the liver and t tendency to hepatitis

For a period while our patient was under treatme the level of urinary arsenic excretion indicated blo levels which would have been associated with sympto of acute arsenical poisoning if the arsenic had not be circulating as an innocuous dimercaprol thioarsenite

Reference must be made to the work of Koppanyi a Sperling (1947), who found that when rabbits were gi sodium arsenite followed by dimercaprol an explosive reacti developed The effect did not occur with arsenates or w arsphenamine It was certainly not due to the final dim caprol thioarsenite, and Koppanyi and Sperling thought was perhaps caused by toxic intermediate compounds T wondered whether, in cases of poisoning with arsenite su as Fowler's solution, the protective action of dimercap might not be accompanied by similar unpleasant side-effec No such side effects were seen in our case

Despite the beneficial effects of therapy, we think likely that the patient's liver has sustained permane damage After eighteen months it remained har though there had been much reduction in its size ow to the removal of fat The plasma globulin was hig at 4 24 g per 100 ml and diffuse hepatic fibrosis w

DETERMINATION OF PROTHROMBIN

Many different methods have been used. Three main methods are here briefly discussed.

Quick's (1945) one-stage method and later modifications thereof (Link-Shapiro, and others) have been most commonly used. Theoretically one can argue against this method that the results depend not only on the amount of prothrombin in the plasma but also on the amount of proaccelerin and proconvertin (Owren 1947, 1951). When the method is used as guidance for dicoumarol treatment, this will not have any important bearing on its dependability, because the concentration of proaccelerin is on the whole hardly influenced by dicoumarol (Owren 1950, Bjerkelund 1950), and the concentration of proconvertin largely follows that of prothrombin during the treatment (Owren 1950, Owren and Aas 1951).

The values found by Quick's method are usually given as prothrombin time in seconds or as prothrombin index. For the reasons mentioned above this is unfortunate and has caused much confusion. A great deal would be gained if everyone, at least in medical papers, could give the prothrombin value as a percentage of the normal. This would make it possible to compare and assess methods and results, which at present is difficult or impossible. Further, in the Quick method the prothrombin time can be converted to prothrombin percentage by the use of a normal curve. The most correct normal curve is constructed by dilution of normal plasma with prothrombin-free human plasma. From this the prothrombin time in different dilutions from 100% down to 10% is decided (Wright and Foley 1947, and others). The curve is logarithmic.

The two-stage method originated by Warner et al. (1936) and later modified by Owren (1947), Ware and Seegers (1949), and others has been generally found too complicated for clinical use, though it is used by a few laboratories. No further mention will be made of it here.

The most practical and dependable method for clinical use is without doubt Owren's one-stage method (Owren 1947, 1949). In contrast to Quick's method, the variations in the concentration of proaccelerin have no influence here. Though Owren's method was at first described as a specific method of prothrombin estimation, later investigations (Owren and Aas 1951) showed that in its original form the method is in reality a combined determination of prothrombin and the new factor proconvertin ("P and P method"). As mentioned above, proconvertin under dicoumarol treatment largely follows prothrombin; the method is therefore ideally suited to the control of dicoumarol treatment and is steadily gaining favour. For details of the method the reader is referred to the above-mentioned papers.

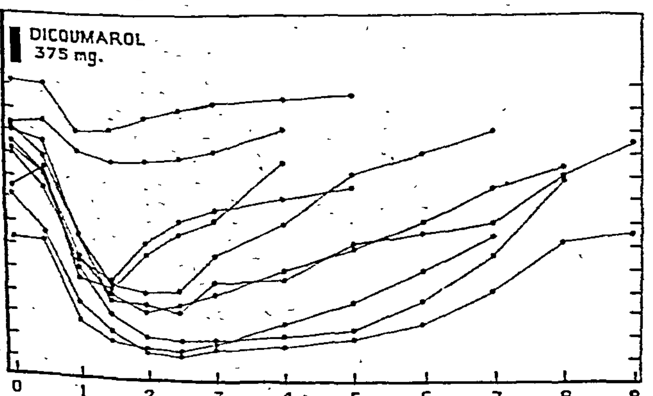

Fig. 1—Effects of dicoumarol 375 mg. on ten healthy persons, showing (1) sensitivity to dicoumarol varies widely, (2) maximal effect develops late, and (3) effect is prolonged.

EFFECT OF DICOUMAROL ON MAN

The main effects of dicoumarol on man are demonstrated by a clinical experiment illustrated in fig. 1 (Bjerkelund 1950). This shows the fall in the prothrombin value of 10 normal persons who received 375 mg. dicoumarol orally. It also shows that: (1) the sensitivity to dicoumarol varies greatly from person to person; (2) the effect appears relatively late, the maximum being first seen after 36–72 hours; and (3) dicoumarol has a long-lasting effect, a dose of 375 mg. lasting in some people up to eight days. These three properties of dicoumarol are most important when it is used therapeutically, and they must be kept in mind in determining the dosage.

When dicoumarol treatment is to be started, one can seldom predict whether the patient is sensitive or resistant to it. The body-weight is no guide, for there is no definite relation between the weight and the requisite dose. The patient's age and general condition may give a hint, because older patients and patients in poor general condition are more sensitive than younger and more robust persons; but even this cannot be depended on; nor has the patient's initial prothrombin value any constant relation to his tolerance of dicoumarol.

That liver disease diminishes the tolerance towards dicoumarol is well known. It has also been shown that the onset of acute hepatitis during prolonged treatment with dicoumarol greatly increases the sensitivity; hence the maintenance dose must be reduced to a fraction of the original dose (Bjerkelund 1951). In liver disease, however, dicoumarol treatment is usually not indicated.

In practice it is therefore wisest to assume that one cannot foretell a patient's resistance toward dicoumarol. Consequently there is no reason to vary the initial dosage for different patients. On the contrary, there are grounds for using fixed initial dosage, because after two or three days the effect of the initial dosage will give the first indication of the patient's tolerance.

We have found that 250 mg. on the first day and 125 mg. on the second day are suitable initial doses, if the treatment is started in the morning. 200 mg. is given if the treatment is started in the afternoon or evening, and 100 mg. is given next morning, because the doses will be closer to one another. (The patients treated in the medical departments at Oslo Municipal Hospital are for the most part older patients with heart ailments. In departments with younger patients, it would, perhaps, be advisable to give somewhat larger initial doses.) Blood for prothrombin estimation is always taken before giving the first dose of dicoumarol. The blood can be examined later with other samples. This is permissible with Owren's method, since the ox plasma used in this method contains a surplus of labile proaccelerin. It is essential to have the patient's prothrombin value registered before treatment is started, because it gives the initial point of the prothrombin curve, which is our most important guide during treatment.

The importance of charting the prothrombin values and the dicoumarol doses for each patient under treatment cannot be exaggerated. If one has once become accustomed to determining dicoumarol dosage by means of such a curve one cannot imagine doing it in any other way. The curve gives us at once a picture of how the day's prothrombin value compares with the previous ones. We can see the effect of the previous days' doses of dicoumarol, and can decide whether they have been sufficient, too small, or too large. One must strongly emphasise that it is not the effect of yesterday's dose but of the many more patients would complain of symptoms in hospital, but the lochia tend to obscure the bleeding at defæcation, and the pain is often attributed to perineal sutures or their recent removal In the present series there were 6 cases in which symptoms came on between the twelfth and thirty-ninth weeks of pregnancy

CASE-RECORD

The following case-record shows how painful anal fissure can be (prolapsed piles were also present) and how very large hæmorrhoids may be cured spontaneously six weeks after delivery

A multipara, aged 27, was admitted, when thirty four weeks pregnant, complaining of "an attack of piles" She said she had had hæmorrhoids for six years On examination two very large hæmorrhoids were seen, one anterior and one posterior In addition there were two acute fissures anteriorly and one posteriorly The hæmorrhoids also prolapsed after replacement, which was extremely painful, in spite of the application of an anæsthetic ointment It was therefore necessary to dilate the anus digitally under anæsthesia After this the stools were kept soft with mist magnesii hydroxidi *B.P* $^{1}/_{2}$ fl oz (14 ml) nocte, and a no 2 St Mark's dilator was passed twice daily lubricated with ung cinchocainæ co *B P C* This relieved the patient's symptoms considerably, but she had to remain in hospital until her spontaneous delivery at term There was no perineal laceration Six weeks after delivery she attended the postnatal clinic, and the only abnormality was a long mucosal and skin tag. It was arranged to excise this when the baby was weaned

PARITY

A primipara is obviously more liable to perineal damage The commonest cause of anal fissure is trauma, and in this series there was no case of a patient with more than two previous deliveries having an anal fissure, 35 patients were primigravid, and 10 had had one previous pregnancy

ANAL FISSURE IN RELATION TO PERINEAL DAMAGE

Perineal damage	Method of delivery	Fissures	Antenatal symptoms
No laceration	Spontaneous	11 cases	2 cases
Episiotomy	Spontaneous	12 ,,	
Episiotomy	Forceps	13 ,,	2 ,,
1st-degree tear	Spontaneous	3 ,,	1 case
2nd degree tear	Spontaneous	4 ,,	1 ,,
	Cæsarean section	2 ,,	

The accompanying table shows that, excluding cases in which symptoms were present before delivery and 2 cæsarean sections, there was damage to the perineum in 28 out of 39 cases 23 of the cases with damage to the perineum had episiotomy, and in 11 cases this was associated with forceps delivery The forceps rate over the period studied was 13 1% in primipara and 3 5% in multipara The episiotomy rate in these two groups was 34 9% and 13 1% respectively

TREATMENT

Treatment was on the lines described by Gabriel (1948) Patients were instructed to maintain a good fluid intake, and constipation was treated with mist magnesii hydroxidi *B P* Liquid paraffin was avoided Digital application of ung cinchocainæ co *B.P C* or ung benzocainæ co *B.P C* twice daily round the anal margin was prescribed in the first instance The ointment was always used before defæcation If this did not bring relief, a no 2 St Mark's dilator was used, lubricated with one of these two ointments, and passed twice daily 34 patients were cured by use of ointment alone, 10 required the use of a dilator, and the case described above required stretching of the sphincter In no other case was surgery or injection of the sphincter necessary, but since this time intractable cases have been seen and referred to the surgical department for treatment The symptoms usually abate within a few days, and the fissure heals completely within two or three weeks In some cases fresh fissures appear a few weeks after apparent cure 3 patients included in this investigation did not atten the follow-up clinic but are presumed cured There di not seem to be any great difference between ung cinchocainæ co *B.P C* and ung benzocainæ *B.P C* i effectiveness, the impression is that the former is le liable to give rise to pruritus

DISCUSSION

Pregnancy, labour, and the postpartum period off many opportunities for the formation of fissure Constipation is common in the antenatal period and may b associated with the excessive use of purgatives Insufficient fluid intake, weak abdominal muscles, and a painf perineum may also lead to constipation in the puerperiu In addition the ritual enemata of the first stage of labou with rectal examinations and the distension of the anu and perineum in the second stage of labour, are ætiologica factors

From the present investigation it can be said that th more traumatic the delivery the more likely is fissure t occur, and that anterior and multiple fissures are ver common in puerperal women This is understandabl and agrees with the views put forward by Lockhart Mummery (1934) He described the external sphincter a consisting of two lateral halves In front the halve are continuous, but posteriorly all the fibres do not joi end to end but are for the most part placed parallel wit each other This arrangement of fibres leaves the posterior commissure least supported, whereas the nex weakest place is the anterior commissure In women th anterior commissure receives less support than in me owing to the presence of the vagina In labour it is mo likely that the anterior commissure will be damaged especially if the perineum is torn or episiotomy is performed This probably explains the large number o anterior fissures seen in the present series

As would be expected, anal fissure is most common i the primiparous patient and is often related to forcep delivery and to perineal damage The commonest tim for symptoms to appear is after discharge from hospital This may be explained by the patient leading a ver sedentary life in hospital and not noticing any increased discomfort on defæcation, especially if she has perineal sutures In the postpartum period the sphincter i nearly always extremely lax and it does not regain it tone until the patient is discharged from hospital. It was thought that patients after discharge might not keep up their fluid intake to the six pints a day recommended in hospital, and that this predisposed to constipation and subsequent fissure In view of this the influence of breast-feeding was investigated, but no significant conclusion was reached The fall in the œstrogen level after delivery may also adversely affect the mucosa of the anal margin, making it less resistant to trauma

It is important to realise that many patients attending the postnatal clinic have distended rectal veins 16 patients complaining of anal fissure had this condition but as soon as the fissure was cured they became symptom-free owing to the tendency of hæmorrhoids to spontaneous remission during the postpartum period In six months only 3 patients were seen at the postnatal clinic with hæmorrhoids requiring injection Hæmorrhoids cause great discomfort in the antenatal period and in the early puerperium, but it must be emphasised here that most of these patients will be spontaneously cured of their hæmorrhoids six weeks after delivery

To confirm the last fact 100 patients were examined in the wards from the first to the tenth day of the puerperium Prolapsed piles are very common, and fissures, although sometimes seen, are difficult to find owing to the excessive corrugations of the anal margin and the presence of lochia Further, the fissures give rise to very little discomfort, owing to the great laxity of the anal sphincter at this time, and, if there is any discomfort perineal sutures or their recent removal will be blamed

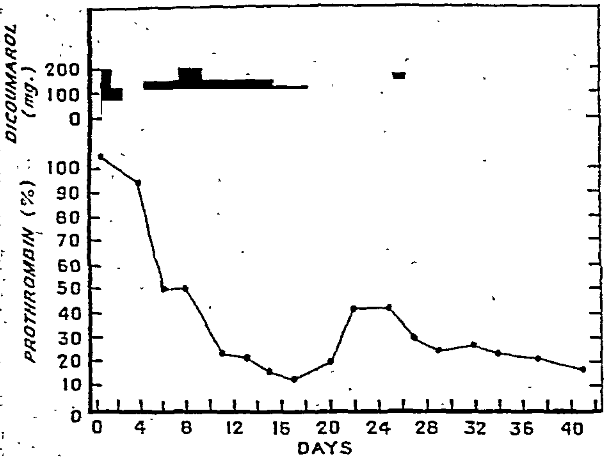

Fig. 5—Adjustment of dosage of dicoumarol according to effect on prothrombin in a man, aged 54, with coronary thrombosis and very resistant to dicoumarol.

By immediately making small adjustments in the dosage in keeping with minor fluctuations in the prothrombin curve, the prothrombin value will be kept as near constant as possible. If one waits for the next laboratory report before adjusting the dosage, one will often find that meanwhile the prothrombin value has risen far above the therapeutic range. This means that a much larger dose must be given, and there will be a delay in reaching the maintenance dosage required to produce a stable prothrombin value.

For this reason it is essential for the dose of dicoumarol in each tablet to be small. In Norway tablets of 25 mg. of dicoumarol are used. Even with these small tablets it will usually be impossible to reach a constant prothrombin value with a definite number of whole tablets each day; often the tablets have to be broken. Variations of 10–20 mg. weekly in the dosage can prove sufficient to change the prothrombin curve. This matter is more fully explained below, in the discussion of long-continued treatment.

CONTACT BETWEEN LABORATORY, PHYSICIAN, AND PATIENT

Quick and dependable contact between laboratory, physician, and patient is essential. Figs. 2–8 show that the prothrombin value is not estimated daily, as has been usual in most hospitals in the past, but at intervals of two or three days. In practice this has proved fully sufficient in view of the long-lasting effect of dicoumarol and the fact that the dosage is based on the shape of the curve and not on the current prothrombin value. Thereby the laboratory is saved much unnecessary work, and the patient many venepunctures. We estimate the prothrombin values three times weekly—on Monday, Wednesday, and Friday. As soon as the laboratory results are to hand, each patient's curve is brought up to date. From the curve, the physician determines the dosage for the two or three following days. The dosage is marked on each patient's diagram and at the same time entered in ward books for the nurse who gives out medicines each morning. Sometimes, as a result of an increase in prothrombin values, it is desirable to give a patient an extra dose on the same day, besides the one he has already received. In such cases the physician gives a direct order to the nurse on duty.

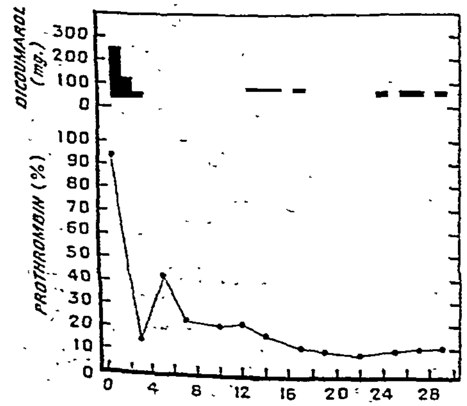

Fig. 6—Secondary rise of prothrombin value owing to too great a reduction of dicoumarol dosage after initial dose, and subsequent adjustment of dosage to keep prothrombin value in therapeutic range in a man, aged 52, with coronary thrombosis.

The system here outlined has proved very satisfactory in practice. It is a great advantage if one can limit the determination of prothrombin to three times weekly.

LONG-CONTINUED TREATMENT OF AMBULANT OUTPATIENTS

Today no article about dicoumarol dosage is complete without mentioning the question of continued treatment of ambulant patients after they have left hospital. In the past two years, in our department of Oslo Municipal Hospital, we have given such treatment to many patients with (1) coronary thrombosis and myocardial infarction, (2) mitral-valve stenosis with auricular fibrillation and a tendency towards embolism, and (3) thrombo-embolic episodes from other causes. It has proved possible to give adequate dicoumarol treatment to ambulant outpatients with estimation of the prothrombin values every week or fortnight. Usually the prothrombin values ought to be estimated weekly from four to eight weeks after the patient's discharge from hospital; later every fortnight will suffice in most cases. It is an advantage to be able to start the treatment while the patient is in hospital, so that the correct maintenance dosage can be reached before he is discharged. On the other hand, there is no objection to starting treatment on outpatients provided that the prothrombin value is estimated and charted every second or third day until the suitable maintenance dosage has been discovered.

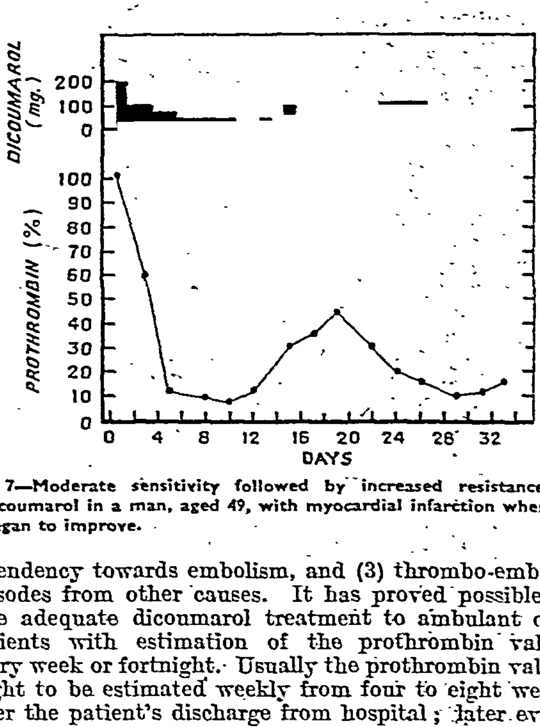

Fig. 7—Moderate sensitivity followed by increased resistance to dicoumarol in a man, aged 49, with myocardial infarction when he began to improve.

Fig. 9 shows the treatment administered, with estimation of the prothrombin value every fortnight for a year in a patient with coronary thrombosis. Throughout that time the prothrombin value remained in the optimum therapeutic range, with only small fluctuations up to 10%. These minor fluctuations must at once be met with an adjustment in the dose, if the best therapeutic effect is to be maintained. The figure shows clearly that an increase or decrease of 25–50 mg. at the fortnightly adjustment of dosage is sufficient to effect the desirable change in the prothrombin curve. If one could give addimarrow biopsy showed hypercellularity, with megaloblastic erythropoiesis A diagnosis of pernicious anæmia in relapse was made

Treatment —The patient was confined to bed for a period of observation and was given a normal ward diet A mixture of 100 ml of R D E -treated gastric juice (see below) and 10 µg of vitamin B_{12} (‘Cytamen,’ Glaxo) was given at 9 P M daily, three and a half hours after the last meal of the day, for five days by mouth

Results of Treatment —Changes in the hæmoglobin values and red cell and reticulocyte counts are shown in fig 2 A reticulocyte response of 35% was observed on the fifth day after treatment began On the fourteenth day the red cell count had risen to 3,600,000 per c mm from an initial level of 1,600,000 per c.mm This represents an optimum response (Ungley and Campbell 1949)

THE GASTRIC JUICE

Student volunteers were used as a source of gastric juice

Collection —A Ryle's tube was passed after an overnight fast, and the fasting juice was discarded Histamine phosphate 0 3 mg was given subcutaneously, and gastric juice was aspirated until 150 ml had been collected from one or more volunteers Before the gastric juice was pooled, a sample was taken from each volunteer and tested with Topfer's reagent for the presence of hydrochloric acid Only gastric juice containing free hydrochloric acid and no bile or blood was used

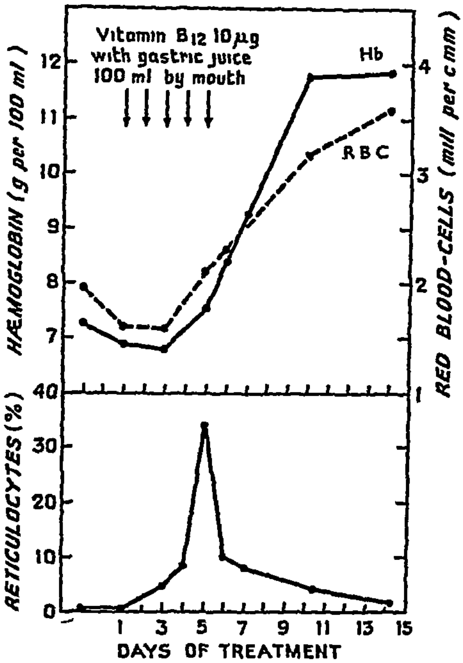

Fig 2—Reticulocyte response, increased amount of Hb, and increased red-cell count after treatment with oral vitamin B_{12} and human gastric juice treated with R D E

Treatment of Juice —The collected juice was covered with a layer of undissolved mucus The 150 ml sample was transferred to a sterile jar and stirred mechanically, while sodium hydroxide was added drop by drop until pH 6 0–6 5 (the optimum range for R D E) was reached The gastric juice was then spun in a horizontal centrifuge at 3000 r p m for fifteen minutes Neutralisation led to the solution of most of the surface layer of mucin After centrifugation 100 ml of the supernatant fluid was mixed with 10 ml of calcium-acetate saline solution (Stone 1949) and with 3000 units of purified R D E prepared by the method of Ada and French (1950) This mixture was then incubated in a water bath at 37°C for an hour, at the end of which samples of the original untreated supernatant fluid and the R D E -treated material were titrated against five agglutinating doses of indicator virus (T MEL) by the technique of Burnet (1948)

The accompanying table shows the results obtained with five samples of gastric juice given to the patient Destruction of the mucous substrate was virtually complete

DISCUSSION

The fact that an optimum hæmatological response was obtained in classical pernicious anæmia treated with oral vitamin B_{12} and neutralised gastric juice incubated with R D E indicates only that, if the intrinsic factor is a mucoprotein, its biological activity is not modified by treatment with R D E In the case of urinary mucoprotein it is known that full action of R D E, while destroying all capacity to react with viruses, leave the serological character unchanged The action is limited and specific, and our failure to obtain inhibition of intrinsic factor by R D E does not in any way diminish the significance of Glass's important work Increased knowledge of the function of these substances is clearly of fundamental importance to the understanding of the physiology of the alimentary tract

RESULTS OBTAINED IN TITRATION OF TREATED AND UNTR GASTRIC JUICE AGAINST INDICATOR VIRUS

Date	Designation	Inhibitor titres to 5 agglutinating doses of T ME	
		Before R D E treatment	After R D E treatm
May 9, 1952	A	5120	<
„ 10, 1952	B	3000	<
„ 11, 1952	C	2560	<
„ 12, 1952	D	3000	<
„ 13 1952	E	6000	<

Pernicious anæmia is uncommon in patients of this age The case demonstrates the value of gastric biopsy in substantiating diagnosis in megaloblastic anæmias thought to be addisonian

SUMMARY

A young woman with classical pernicious anæmia in relapse was treated with oral vitamin B_{12} and human gastric juice acted upon by receptor destroying enzyme (R D E) A normal therapeutic response was obtained

Although there is good evidence that intrinsic factor in gastric juice is a mucoprotein, it is not one which is inactivated by R D E , thereby differing in its properties from gonadotrophin and mucoproteins derived from respiratory-tract cells

We are grateful to Dr Ian Wood, head of the clinical research unit, for his help and advice in this work, and Dr E S Finckh, pathologist, for his histological studies

“*The time is overdue for more active participation by physiologists as consultants to clinical services in teaching hospitals Such a development could become a tremendous boon to clinical medicine I think that physiology would profit equally thereby there might come to be two groups of physiologists—the experimentalists in general physiology as now, and an equally important division, whose members would spend a definite, if not a major, portion of their time in the wards and laboratories of teaching hospitals Physiologists have machine shops for the development of tools necessary in the prosecution of their experiments Why not machine shops in which the physiologist may develop precision instruments for the study of disease and its care in man? What if physiology did become the handmaiden of medicine? Would physiology suffer? I do not think so*”—OWEN H WANGENSTEEN, *Proc Mayo Clin* 1952 27, 532

DISCUSSION

It should be evident from the reasons given above at maintenance dosage is more desirable than intermittent dosage because (1) it is more logical; (2) experince has proved it to be a practical and adequate method administering dicoumarol in hospitals; and (3) it is made possible a safe and effective treatment for [illegible]ts. It is therefore difficult to under- [illegible] and Weiner (1951) advocate intermittent dosage. Despite their great experience their guments in this connection do not seem sound.

They demonstrate in a diagram the treatment of one patient ith intermittent doses. Three doses are given with ten-day tervals, the first 600 mg. and the second and third 400 mg. ich. They claim to have obtained satisfactory results with iese doses. (The fluctuations of the prothrombin values en in the diagram cannot be ascertained by the reader, r the values are not given in percentages of the normal.) n order to compare the two methods of administration, the atient then receives 50 mg. daily for five days (equalling 00 mg. with ten-day intervals) as a maintenance dosage. No large initial dose which could bring the prothrombin value the therapeutic range is given.) As the mentioned mainenance dosage is insufficient to decrease the prothrombin alue satisfactorily, Shapiro and Weiner administer 100 mg. aily on the following four days; in fact they double the dose. he prothrombin value then decreases after a couple of days o a dangerously low level. I have shown here how even inor changes in the dosage can increase or decrease the rothrombin value considerably. It is therefore not surprising hat doubling the dose has the effect already mentioned. If he same principle were used for intermittent dosage, Shapiro nd Weiner would certainly also have produced very low rothrombin values by suddenly administering double doses ith the same time interval.

It seems clear that intermittent dosage is entirely unsuitable for treating ambulant patients with infrequent estimations of prothrombin.

CONCLUSION AND SUMMARY

One must conclude that at present there is only one rational method of giving dicoumarol—namely, maintenance dosage.

For this purpose an exact and dependable method of estimating prothrombin is necessary. Owren's method is especially recommended.

It must be kept in mind that the effect of dicoumarol appears slowly, lasts long, and varies greatly between one patient and another (fig. 1).

The same initial dosage (250 mg. on the first day and 125 mg. on the second day) may be used for all patients. The effect of the initial dosage is seen after two or three days and gives the first indication of the patient's tolerance. Thereafter the dosage should be adjusted according to the shape of the curve of prothrombin values (not the current prothrombin value). Large variations in the dosage from day to day should be avoided as much as possible while trying to reach the correct maintenance dosage.

Dependable contact between laboratory, physician, and patient is essential.

The dicoumarol dosage should be adjusted immediately even to minor fluctuations, not only in treating hospital inpatients but also in treating ambulant outpatients with infrequent estimations of prothrombin. An increase or decrease equalling 2–4 mg. a day is often enough to provoke a distinct fall or rise in the prothrombin curve after 8–14 days.

If an immediate anticoagulant effect is desired, heparin should be used with dicoumarol until the prothrombin value has reached the therapeutic range.

HYDATID DISEASE

SEROLOGICAL REACTIONS WITH STANDARDISED REAGENTS

H. J. BENSTED
O.B.E., M.C., M.R.C.P.
LIEUT.-COLONEL, R.A.M.C. RETD; DIRECTOR OF LABORATORIES

J. D. ATKINSON
F.I.M.L.T.

From the Central Public Health Laboratory, Colindale

HYDATID disease is not generally considered to be a common condition in this country; but the fact that the Central Public Health Laboratory has issued during the last two years more than 600 doses of antigen for the intracutaneous or Casoni test suggests that the possibility of the disease is not infrequently considered when there is radiological evidence of a mass in the thorax or abdomen. Doubtless the test is often undertaken as a routine exclusion test; for in only 90 of these cases was information and/or material obtained for additional investigation. Of these, 28 were reported as having a completely negative Casoni reaction and adequate information was given for regarding the condition as other than hydatid disease. The remaining 62 cases were fully investigated, complement-fixation reactions were performed, and the final diagnosis was supported by the results of surgical procedures.

The usual definitive host of the *Echinococcus granulosus* is the dog, and the intermediate hosts are commonly cattle and sheep, although other mammals, including man, may serve. Dogs whose feeding is uncontrolled, and particularly farm dogs which may have access to local slaughterhouses, are more liable to harbour this tapeworm. Farmland in and around the farm may be heavily contaminated with egg-laden fæces, and the coats of all animals lying or rolling on such contaminated ground will be likely to pick up ova. People handling these animals may readily transfer the ova to their fingers, and unless a high standard of personal hygiene is maintained it is not difficult for the ova to gain entrance to the alimentary canal and set up an infection by the liberated embryo migrating to some organ or tissue where the hydatid can develop fully. This indirect route is generally regarded as a commoner way for human infections to be contracted than by direct contact with an infected dog.

A large proportion of the cases of hydatid disease seen in this country appear, from their history, to have been contracted overseas; but a significant number can be traced to South Wales. Wolfe (1943) found that 0·5% of the sheep killed in one slaughterhouse in Cardiff were infected with hydatid cysts. Among the 62 cases investigated in our series there were 42 cases of proved hydatid disease, and one-quarter of the patients lived in Wales, while nearly half had spent periods of their life in the Middle or Far East.

Reviews of Books

Viral and Rickettsial Infections of Man

2nd ed Editor THOMAS M RIVERS, M D, director of the hospital, the Rockefeller Institute for Medical Research Philadelphia and London J B Lippincott 1952 Pp 719 60s

THE second edition of Rivers is about half way in size between some recent pocket-size textbooks of virology and a well-known portmanteau-size reference book It combines successfully the readability of the former with the erudition of the latter In his preface Dr Rivers suggests that the book may fulfil a need of medical students and practising physicians, but it seems unlikely that many of these busy people will have time to study another new specialty in the detail provided here The book should appeal much more to bacteriologists, research students, and others interested in learning or teaching virology, and to physicians and public-health workers specialising in the treatment of infectious diseases It is beautifully printed and illustrated and should be a great help to many would-be virologists in distress

This omnibus of virology carries contributions from many well known experts (In this case an expert is one who has spent considerably more than the customary one year period studying his subject) The first nine chapters describe general aspects of the study of virus diseases, physical, chemical, and serological techniques, methods of cultivating viruses in fertile eggs and tissue cultures, epidemiology, interference between viruses, and diagnosis Then follows an excellent chapter on bacteriophages, which earn their inclusion in a textbook of viral infections of man by the important light they have thrown on methods of virus multiplication After these lengthy preliminaries we come to the individual virus diseases, and it is good to see that for once the patient and the epidemic receive more attention than the virus This book is supported by a grant from the National Foundation for Infantile Paralysis, which may perhaps explain the greater respect paid to neurotropic than to respiratory virus diseases Chapters on hæmagglutination by Hirst, epidemiology by Maxcy, rabies by Johnson, and yellow fever by Theiler are all that could be wished for An otherwise excellent chapter on poliomyelitis is spoilt by its cursory treatment of tissue culture techniques in the study of this disease Some chapters tend to be more autobiographical than is desirable in an objective account of research, and here and there will be found odd sins of omission and commission This edition is brought up to date with accounts of cat scratch fever and of diseases caused by the Coxsackie viruses, and it is obvious that a big attempt has been made to refer to all the latest advances

Osteo-arthritis of the Hip

W ALEXANDER LAW, O B E, M D, F R C S, assistant orthopædic surgeon, London Hospital, associate surgeon, Robert Jones and Agnes Hunt Hospital, Oswestry. London Butterworth 1952 Pp 87 25s

ALTHOUGH this little monograph surveys briefly the causes and treatment of osteo arthritis of the hip, it is mainly concerned in reflecting Mr Law's well-known interest in its management by vitallium cup arthroplasty In a very personal account of case-histories and technique he shows just what success can be obtained by meticulous attention to the details of case-selection, operation, and aftercare, though perhaps he does not make it sufficiently clear that this procedure is essentially one for the superlative technician, and that, in average hands, the acrylic prosthesis may yield good results with less expenditure of effort

Le trachome

ROGER NATAF, ophtalmologiste des Hôpitaux, membre associé de l'Institut Pasteur de Tunis Paris Masson 1952 Pp 426 Fr 3700

THE name of Dr Nataf and that of his collaborator Dr Cuenod is already well known to ophthalmologists for biomicroscopical investigations of the conjunctiva, which has included much work on trachoma Now Dr Nataf, working at the Institut Pasteur of Tunis, gives us a complete account of trachoma in all its possible ramifications, even including its medicolegal aspects Dr Jean Sedan also contributes a chapter on the physiopathology of the trachomatous eye

In the British Isles trachoma is hardly a problem for few new cases arise, and treatment is almost confined to the late complications of trachoma contracted elsewhere, but in the Middle and Far East trachoma remains the major ophthalmic scourge, responsible for more blindness than any other ophthalmic disease The medical world at large will, therefore, be grateful to Dr Nataf for his excellent monograph, which gives us all the benefit of the 25 years he has spent studying this condition

Manual of Electrocardiography

B F SMITH, M D, professor of clinical medicine, Baylor University College of Medicine New York and London Elsevier Press 1952 Pp 215 32s

THIS is a description of electrocardiography reduced to the smallest compass, but every word is to the point The principles are clearly set out and applied to the explanation of many abnormal tracings, giving the student for higher examinations and the general physician an insight into the way in which most abnormalities are caused This will also be appreciated by the cardiologist who can also occupy himself by considering how he would explain those changes, particularly in the T waves not covered by the author There is little to criticise, but the advice on precordial leads is out of date, some of the tracings are of poor quality and in none of them are the waves labelled, and there are a few typographical errors A quarter of the book contains tracings from patients, accompanied by the post-mortem reports, but without comment or explanation, the reader being left to make his own correlation This is an excellent feature, but the final chapter, entitled "Pen Pictures of Cardiology," is out of place

Infant Development

The Embryology of Early Human Behaviour ARNOLD GESELL, M D London Hamish Hamilton 1952 Pp 108 21s

OVER a period of thirty-five years, Dr Gesell has produced no less than twenty-five books on his chosen subject, besides the films he has used to an increasing extent in demonstrating facets of early human development *Infancy and Human Growth*, which appeared a quarter of a century ago, was an important pædiatric landmark, and did much to stimulate other workers in the same field With the passage of the years, and the development of cinematography, the author's publications appear to have become, to an increasing extent, running commentaries, and to describe the present volume as "the book of the film" would be less inaccurate than when a similar description is applied to, say, *Kidnapped* or *War and Peace* The style at times is perilously near the pompous, and many will prefer the author's earlier writings

---

Symptoms and Signs in Clinical Medicine (5th ed Bristol John Wright & Sons 1952 Pp 480 35s)—It is five years since the last edition of Dr E Noble Chamberlain's popular textbook appeared As before, there are many illustrations most of them clear, well chosen, and helpful to the text Many chapters have been revised and one or two completely rewritten, including that on medical operations and investigations, a particularly useful part of the book A new feature, much to be welcomed, is a short glossary showing the origin and meaning of many of the words which all students have to meet for the first time

The book is likely to remain a valued friend to student, houseman, and practitioner

Gynecologic and Obstetric Pathology (3rd ed Philadelphia and London W B Saunders 1952 Pp 595 50s)—Prof Emil Novak's well illustrated textbook emerges in good form from a thorough grooming at the hands of its careful author The sections on carcinoma of the cervix, hydatidiform mole, chorionepithelioma, and several other topics have been revised to express modern opinion, and there is an informative new chapter on diseases of the breast—an organ which gynæcologists have only recently discovered The pictures are as good as ever, and nearly a hundred new ones appear in this edition—some of them replacing less successful earlier versions of the same subjects

TABLE I—COMPLEMENT-FIXING TITRES OF CYST FLUIDS

„ IV	+ + +	+ +	+	−	−	−	−

xing antibody. and Hiles (1926) reported that horses nd rabbits were unsatisfactory. We ourselves have xamined the sera of horses with hydatid infestation nd have not found any significant complement-fixing ntibody; but we have not attempted to immunise these nimals with suspensions of scolices. Our experience with abbits has confirmed Hiles's (1926) findings that a high roportion of the sera from uninoculated rabbits conained some natural substance which in the presence of ydatid antigen fixed complement.

Guineapigs, although not convenient animals for the reparation of large amounts of immune serum, proved o be suitable. A batch of selected guineapigs was herefore given a series of injections of a suspension of round-up scolices from a fresh hydatid fluid and then led out. The sera were tested individually and without xception found to have reasonably high titres of complenent-fixing antibody. They were later pooled for final esting and use as a standard serum.

Attention has already been drawn to the method of ssessment of antigenic potency employed by Hamilton airley (1922) and the consistent results he reported in omparative tests on pooled sheep-cyst fluids rich in colices. While this may be true with large pools of heep's fluid, we have not found that individual cyst luids from either ovine or human sources give such onsistent results. Table I shows the complement-fixing itres of a number of fluids (all of which appeared to be equally rich in scolices) when examined with the same standard serum.

Fluids deficient in scolices, however, were consistently poor as antigens. Two fluids from horses, one from a sheep, and one from a human source failed to fix complement with the standard serum diluted more than 1 in 2, and several human fluids have proved to have very low antigen content.

TABLE II—ANALYSIS OF 62 CONSECUTIVE CASES OF SUSPECTED OR KNOWN HYDATID DISEASE IN WHICH THE FINAL DIAGNOSIS WAS CONFIRMED BY EXAMINATION OF THE CYST FLUID OR BY SURGICAL OPERATION

Type of case	Total no.	C.F.T. and skin test positive	Only C.F.T. positive	Only skin test positive	Both tests negative
Primary uncomplicated cyst of liver—					
Before operation	23	18	3	1	1*
1 year or more after operation..	4	1	2	0	1†
Cyst of lung—					
Before operation	6	6	0	0	0
1 year or more after operation..	7	7	0	0	0
Mesenteric cysts—					
After operation	1	1	0	0	0
Bone—					
After operation	1	1‡	0	0	0
Suspected hydatid proved at operation to be due to other causes..	20	0	0	0	20

C.F.T. = complement-fixation test.
*No antigen found in cyst fluid.
†Both skin test and C.F.T. positive 18 months previously.
‡C.F.T. + + 1 in 64; Casoni positive with one antigen, negative with 2 others.

INTRACUTANEOUS TEST

The history of the intracutaneous test for hydatid disease, introduced by Casoni in 1911, is very similar to that of the complement-fixation test in regard to the varying opinions as to its reliability.

The variation in the potency of different hydatid fluids was recognised, but the reason for this was not appreciated until Hamilton Fairley (1922) showed that the antigen was derived from the scolices. The potency of the Casoni fluid prepared by Kellaway and K. D. Fairley (1932) was assured by using hydatid fluid from uncomplicated sheep cysts rich in scolices and then by extensive comparative clinical trials in selected patients. This method of standardisation is still undertaken by the workers at the Royal Melbourne Hospital, Australia. In this country it has not been easy to follow this practice, owing to the difficulty of obtaining satisfactory supplies of sheep antigen. Kellaway and Fairley indicated that human antigens were less satisfactory than those from sheep, and Graña (1945), in an extensive review of the literature, expressed the same opinion. They may well be right; indeed one or two human fluids in our series which proved to be equal to the standard antigen in the complement-fixation test were found to be less sensitive in the skin test. Nevertheless it has been possible to obtain some human fluids which, both by the complement-fixation test and by parallel skin tests in suitable patients, have been found to be the equal of the standard sheep fluid.

TABLE III—COMPLEMENT-FIXATION AND SKIN TESTS. CASE OF UNCOMPLICATED CYST OF LIVER

Antigen	Serum	C.F.T. result
Standard	Standard	1 in 64
Standard	Patient's	1 in 16
Patient's	Standard	1 in 64

Skin test: weak positive.

In this country most readings of Casoni reactions are, of necessity, undertaken by different observers; and this makes it difficult to give comparable values to the records received, even when careful measurements of the skin reactions are taken. Using three antigens of the same potency, when assessed as complement-fixing reagents, there has been appreciable variation in the results of the parallel skin tests as recorded by different observers.

The difficulty of obtaining consistent results in the reading of any skin sensitivity tests by different observers, even when it is feasible to standardise a large batch of the antigen with a fair degree of accuracy, has been made clear in the recent report of an M.R.C. National Tuberculin Survey (Medical Research Council 1952). In the case of the Casoni test, where the supply of any one batch of antigen may be strictly limited, the difficulties are even greater, more especially when the only ancillary laboratory test depends on an antigen-antibody reaction which may not represent exactly the same complex as those involved in the intradermal reaction.

On 5 occasions, in which the complement-fixation reactions were positive in serum dilutions of 1 in 16 or more, the patients were skin-tested with two different antigens. The two antigens appeared to be equally potent when examined with the standard serum for complement-fixing antibodies, yet in each case only one gave a definite positive skin reaction. In 4 cases antigen I was superior but in the 5th case antigen II was reported to be the one giving the positive reaction.

In comparing the value of the intradermal test with the complement-fixation test in hydatid disease we have, in table II, included only those cases in which the records and clinical histories have been reasonably complete and in which both tests were performed. During the period there were 4 cases reported as having negative skin reactions in which a hydatid cyst was found at operation.

patient arrangements, and at the Middlesex Hospital Brigadier HARDY ROBERTS has found it helpful to hold outpatient staff conferences, which can sometimes solve problems previously deemed insoluble

Unfortunately it is very hard to organise improvements in an outpatient department (or in any other concern) which is already overburdened by numbers, and, though most references to hospital are perfectly reasonable, it is possible that practitioners could help to make conditions better if they exercised their right of consultation a little more sparingly Sir JAMES SPENCE found that a meeting with general practitioners to discuss doctors' letters was well received, and if B M A meetings were held to consider local problems they would bring out many constructive criticisms and help everyone concerned Alternatively, the subject could be considered by the local liaison committee, where such exists Another and very important means of reducing the pressure on consultative outpatient departments is to provide "direct access" for practitioners to pathological and radiological investigations—an arrangement which is greatly appreciated and rarely abused In practice it is found that the special departments have very little extra work to undertake

In all such arranging, the standpoint of the patient needs to be kept in mind Good signposting is a help to the newcomer, and so is the assistance of receptionists in the entrance-hall to promote the regular flow of patients with their notes The use of trained nurses for such work is quite unjustifiable, and the duties of outpatient nurses should be restricted to assistance with medical procedures Wherever possible departments should come to the patient and not vice versa thus a circuitous journey to the pathological laboratory may be avoided if accommodation is provided in the outpatient department where the common pathological tests can be made Similarly ancillary medical staff such as dietitians should have accommodation in the department to enable them to attend various clinics But the main consideration is that good facilities for outpatient consultation should enable the consultant both to provide guidance to patient and doctor and at the same time to reinforce the patient's confidence in what is being done for him

Prevention of Rheumatic Fever

RHEUMATIC fever is a manifestation of infection of the upper respiratory tract with group-A *hæmolytic* streptococci More than twenty years of epidemiological and immunological investigation support this statement, and, although we know disappointingly little about the details of the relationship, present methods of preventing rheumatic fever are based on the inference that control of streptococcal respiratory infection will reduce the incidence of primary and recurrent rheumatic attacks The results of clinical trials of prophylaxis with sulphonamides or penicillin suggest that this inference is justified

In the United States streptococcal infections and rheumatic fever reach a peak during the early spring The American Heart Association's committee which has been studying the prevention of rheumatic fever has therefore chosen this moment to publish its recommendations, which are being widely distributed to doctors, medical societies, health departments, and medical ancillaries, as part of a general campaign for the prevention of this disease The statement, which we reproduce on p 285, is a useful and simple account of the use and hazards of sulphonamides and penicillin in the treatment of streptococcal respiratory infections in general, and in the prevention of streptococcal infection in rheumatic subjects In England and Wales the peak of streptococcal infections comes later in the year than it does in the United States both scarlet fever and rheumatic fever are usually commonest during the last quarter of the year[1] The American statement is none the less a timely reminder of what can be done the application of a general policy designed to prevent rheumatic fever in this country remains of the first importance, for, quite apart from recurrences induced in rheumatic patients, rheumatic sequelæ probably complicate 1–2% of streptococcal upper respiratory infections The main points made by the committee are now well established, but they cannot be given too much emphasis In the *treatment* of streptococcal infections, intramuscular procaine penicillin, given early and continued until the organisms are eradicated from the throat, has amply proved its worth[2] Sulphonamides are not recommended, and oral penicillin gets second place for though it is known to be useful its reliability for this purpose has not yet been sufficiently widely assessed In the *prevention* of streptococcal infection in rheumatic subjects, the population at risk includes all those under the age of 18 who have had rheumatic fever or chorea, and also all those over this age who have had an attack within 5 years, for the risk of recurrence seems greatest within this period[3] The problem here is a much bigger one than that of treatment prophylaxis should be applied continuously within these age-limits—an expensive business—and partly for this reason the choice of the American authorities has fallen on sulphadiazine Patients in hospital recovering from acute rheumatic attacks may be successfully launched on their course of sulphadiazine, but their supervision as outpatients afterwards calls for considerable organisation Toxic effects, though rare after the first 8 weeks of prophylaxis, should be watched for, routine examination for signs of rheumatic recurrence should be carried out, and it is probably desirable to test the urine occasionally to make certain that the drug is being taken Although resistant streptococci have appeared—with devastating results—when mass prophylaxis has been applied to closed communities under Service conditions,[4] in the individual rheumatic patient taking sulphadiazine at home the risk is not nearly so great

But sulphonamides have their shortcomings, and the superiority of penicillin in exerting a bactericidal rather than bacteriostatic action, in effectively eliminating the streptococcal carrier state, and in only rarely producing penicillin-resistant streptococci has prompted a search for practicable methods of penicillin prophylaxis Penicillin has been given orally, but there are disadvantages it is a more

TOXIPATHIC HEPATITIS DUE TO FOWLER'S SOLUTION

A CASE TREATED WITH DIMERCAPROL

H. J. WADE
M.D. Manc., M.R.C.P.
YSICIAN TO SALFORD ROYAL HOSPITAL AND PARK HOSPITAL, VYHULME; CLINICAL LECTURER IN MEDICINE IN THE UNIVERSITY OF MANCHESTER

E. S. FRAZER
M.B. Manc., M.R.C.P.
SISTANT PHYSICIAN, SHOTLEY BRIDGE HOSPITAL, CO. DURHAM; RMERLY SENIOR REGISTRAR, PARK HOSPITAL, DAVYHULME

Thomas Fowler published in 1786 his "Medical ports of the effects of arsenic in the cure of agues, mitting fevers, and periodic headaches" and therein troduced the solution of 1% arsenic trioxide which has nce borne his name. This solution is now little used general medicine but is often prescribed as a palliative r dermatological conditions. Our purpose here is) to draw attention to its toxic effects and (2) to discuss e treatment of toxipathic hepatitis with dimercaprol.

TOXIC EFFECTS OF FOWLER'S SOLUTION

Peripheral Neuritis.—Déjerine (1883) showed that e nerve condition characteristic of arsenic poisoning as a multiple neuritis essentially similar to alcoholic euritis. The "biochemical lesion" responsible is n inhibition of the pyruvate oxidase enzyme system avrilescu and Peters 1931). This system may be hibited negatively by lack of the co-enzyme thiamine itamin B_1) or positively by the combination of trivalent rsenicals with SH- groups in protein components of he system. Arsenical poisoning thus produces a olyneuritis similar to that seen in thiamine deficiency.

Pain and paræsthesiæ may be intense. In addition o the usual mixed form, with motor and sensory paralysis here is a pseudotabetic form with little motor paralysis Ross and Bury 1893, Harris 1926). The cranial nerves re occasionally involved (Kinnier Wilson 1940). The apidity with which symptoms may appear is illustrated y a case quoted by Harris (1926) in which severe polyeuritis with bilateral wrist and foot drop followed the aking of Fowler's solution 15 minims t.d.s. for six eeks. Recovery is said to be complete in 97% of cases. ut it may be delayed for two years or more.

Epitheliomata.—Inorganic arsenic is now known to ave carcinogenic properties, and Goeckerman and Vilhelm (1940) state that a 1 in 40,000,000 solution of rsenic will change embryonal cells to tumour cells. Arsenical keratoses, first described by E. Wilson (1868). sually occur on the palms and soles but may occur lsewhere. They are prone to malignant change and uch change may be multiple. Epitheliomata are in act said to develop in 20% of keratoses. Ayres and Anderson (1934) examined the palms and soles of each patient with a basal-cell epitheliomata and by this means detected unsuspected cases of chronic inorganic arsenical poisoning. Goeckerman and Wilhelm (1940) mention an interesting case of malignant papillomata of the bladder and ureter in which the lesions were found to contain crystals of arsenic sulphide, and these were present twenty-one years after the patient had taken Fowler's solution over a long period.

Toxipathic Hepatitis.—This term was introduced by Himsworth and Glynn (1944) to describe the hepatic lesion produced by the direct action of a noxious agent, whether a chemical such as inorganic arsenic or a living organism such as the virus of infective hepatitis.

Experimental work on the effect of inorganic arsenic on the liver was done by Ziegler and Obolonsky (1888), Wolkow (1892), Stoeber (1936), and von Glahn et al. (1938). Similar results were obtained by all observers. In rabbits and guineapigs fatty change in the liver cells were seen after a few days; they progressed to necrosis in two weeks, and shortly after this there was an increase in connective tissue with proliferation of bile-ducts in the animals which survived. Such a process in man would lead to diffuse hepatic fibrosis or to multiple nodular hyperplasia, depending on whether zonal or massive necrosis had taken place.

The first report suggesting that hepatic damage could be caused in man by inorganic arsenic was that of Bang (1774) under the title of "De hydrope ex ingesto arsenico observatio." Cases of cirrhosis due to this cause have since been described by Hutchinson (1895), Geyer (1898), Hamburger (1900), Sturrock (1900), Reynolds (1901), Stockman (1921), O'Leary et al. (1928), Rolleston and McNee (1929), Weir (1930), Chapman (1931), Osterberg (1935), and Cannon (1936). The most recent report is that of Himsworth who, in his Lowell lectures of 1947, cites the case of a woman who had taken Fowler's solution for twenty years for psoriasis and fourteen years later was found to have hepatic cirrhosis. No other ætiological factors were evident.

Though it is now fully established, both experimentally and clinically, that inorganic arsenic may cause toxipathic hepatitis and fibrosis of the liver, this is not clearly indicated in standard textbooks. Cushny (1947), for example, mentions that "some swelling of the liver and jaundice may occur but these are not generally well-marked"; Price (1946) merely says that "ascites and general œdema occur towards the end"; and neither Taylor (1948) nor Cecil (1947) describe liver damage in inorganic arsenic poisoning.

CASE-REPORT

A 40-year-old butcher was first seen on March 31, 1949, with an indefinite complaint of lack of joie-de-vivre.

History.—For the previous nineteen months he had suffered from dermatitis herpetiformis, the onset of which had been closely related to an emotional upset. Treatment with a mixture containing Fowler's solution 4 minims given three times daily had commenced in December, 1947, and the amount had been increased to 6 minims in January, 1948, to 7 minims in September, 1948, and to 8 minims in January, 1949. The total intake of Fowler's solution had been 144 drachms, which contains 80 grains of arsenic trioxide. This treatment had kept the skin lesions under control but they had never cleared.

His diet was good and his alcohol intake amounted to no more than an occasional glass of beer. He had never

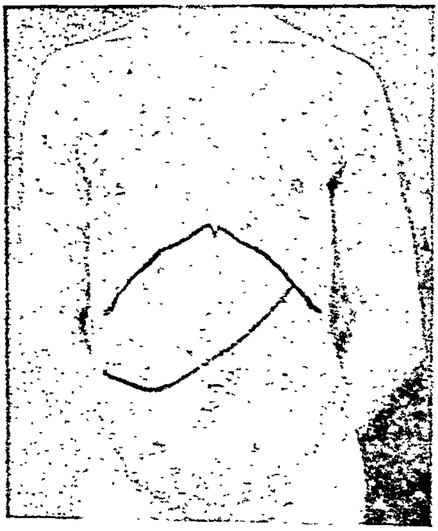

Fig. 1—Showing dermatitis herpetiformis, raindrop pigmentation, and liver enlargement.

It is true, no doubt, that society wishes to be avenged on evil-doers , for in this way an inner tension is released and public anger is assuaged Those seeking to restore judicial flogging also take this human desire for vengeance into account Some, indeed, argue that this kind of emotional release helps to prevent aggression appearing in less controllable forms—as war, for instance But history does not seem to support this opinion in the days of abominable public executions—burnings, quarterings, breaking on the wheel—wars were as common as now, and the atrocities done in wars of our own day have been of the same ugly pattern as those done at the sacking of ancient cities On the contrary, an appetite for cruelty grows by what it feeds on wide experience of brutality does not fit a man to be humane Moreover the enjoyment of other people's suffering is, like other vices, infectious people respond insensibly to the standards of those around them, and can be oriented to base pleasures quite as readily as good ones Whether an execution is actually seen or merely imagined, the mental effect is qualitatively the same, and in our view the perpetual public preoccupation with the condemned cell and the gallows is harmful to the mental health of society

To the English, at any rate, revenge is seldom a fully satisfying experience , it carries too much guilt with it In the case of Bentley the public sense of guilt seems to have been strong—far stronger than the desire for vengeance The youth of the prisoner, the fact that he did not fire the shot, and that he was angry and excited when he shouted to Craig, have carried weight with a generation which is beginning to have a shadowy new conception of the nature of adolescence In this first change of life the endocrine imbalance is expressed in symptoms ranging from noisy laughter, group enthusiasms, fantasy, exhibitionist attire, and transient homosexual attachments to such graver manifestations as manic and schizoid episodes, delinquency, and crime In the case of the Trowbridge boys a fantasy is suggested by their purchase not only of firearms and knives but of a tent, and some similar factor may have been at work in Bentley's case An element of fantasy in a crime neither excuses nor fully explains it, but it may throw some light on the mechanism Daydreaming generally puts the dreamers into positions of success and power, but these are attained quite as often through virtue, courage, and brilliance as through lawlessness or oppression of others If fantasies of easy success through ruthless action persist to an age when they should have been outgrown and are expressed in antisocial deeds, where does the blame lie ? Granted free will, much of it lies, of course, on the youth himself He has chosen his antisocial fantasies, and has resisted good advice and other influences guiding him into socially acceptable behaviour On the other hand, society shares the blame for not providing him with worthier objects for his fantasies, for not giving the good advice with more authority and enthusiasm, and for failing to train him successfully in citizenship Part of the emotion over Bentley's fate can doubtless be identified with a morbid taste for executions, acceptably disguised , and part sprang from an illogical idea that (since he did not fire the shot) the rules of fair play had been infringed But part at least was an acknowledgment of society's share in the responsibility and that is as it should be

Annotations

CONTROL OF DRUG SALES

It is manifestly undesirable that pharmacological potent substances should be freely accessible to t public The supply of poisons has been restricted f over a century , but the rise of chemotherapy, a notably the introduction of the sulphonamides a penicillin, increased temporarily the tendency to se medication with compounds that should be used wi care Soon the sulphonamides were scheduled as poisons and in 1947 a special Act was passed to curb the ind criminate use of penicillin Under this Act the sale a supply of penicillin products was restricted so that th could be obtained only on prescription or for treatmen by, or in accordance with the directions of, a medic practitioner Later a similar ban was placed on strept mycin, aureomycin, and chloramphenicol Now th Therapeutic Substances (Prevention of Misuse) Bill ha been introduced into the House of Lords, to modify th Penicillin Act by permitting any therapeutic substan to be subjected to the provisions of that Act if it appear "to be capable of causing danger to the health of th community if used without proper safeguards" An specific substance would be controlled by regulation b only after consultation with the Medical Research Counc The prospective regulations will presumably make litt change in medical practice, since the Penicillin Act itsel has had no hampering effect , but these regulations wi help to save the public from mishaps through uncontrolle use of substances whose supply cannot be regulate under the poisons law—phenylbutazone, for exampl may be named in them The Bill also seeks power t relax the regulations of the Penicillin Act so that it ca be used for agricultural purposes—presumably th fattening of livestock

MATING AMONG VIRUSES

The demonstration by Delbrück and Bailey[1] tha bacteria simultaneously infected with two different ba related bacteriophage strains yielded progeny wit characters derived from both "parent" phages wa received with unusual interest At once a great deal o speculation on the methods of virus reproduction wa aroused Hershey and Rotman[2] kept the pot boilin briskly with their detailed studies of the mating habit of a group of bacteriophages From an analysis of th numbers of recombinants among the progeny fro different "parent" phages, they were able to construc what are virtually chromosome maps for the particula "genes" which they investigated The possibility o carrying out similar studies with influenza viruses ha lately been engaging the attention of Burnet and hi colleagues in Melbourne

Burnet and Lind[3] found that when a mixture of a influenza virus (MEL) with a neurotropic influenza varian (NWS) was inoculated intracerebrally in mice it wa possible to recover from the mouse brain a virus bearing the serological characters of MEL and the neurotropic properties of NWS They suggested that recombination analogous to that described for bacteriophages, had take place But there was another possible explanation fo these results , the "recombinant" might simply hav been a neurotropic mutant of MEL which would grow happily in the mouse brain, the mutation being in some way favoured by the presence of the NWS In an attemp to exclude this possibility, Burnet et al[4] have now looked for evidence of recombination in viruses grown

robably in progress. Himsworth (1947) emphasises he difficulty of deciding clinically when the stage of ncomplicated fatty infiltration has passed and the tage of fibrosis has definitely begun. The matter can e settled by liver biopsy, but there were non-medical ontra-indications to this investigation in our patient. Himsworth believes that diffuse hepatic fibrosis may ake decades to develop and he remarks that it is ompatible with years of reasonable health. Our patient will probably remain in good health until symptoms of portal hypertension appear.

Reactions to Fowler's solution may cause death or ong illness, and there is now, we believe, no justification for the long-continued administration of arsenic in general medicine. If advantage is to be taken of the [illegible] effect of Fowler's solution in dermatological [illegible], the necessity for careful clinical control must be appreciated. This will involve, as a minimum, examination for hyperkeratosis, inquiry regarding the subjective symptoms of peripheral neuritis, and abdominal examination to detect liver enlargement due to fatty infiltration. If, in a busy dermatological department, careful follow-up is not practicable, it is most unwise to use inorganic arsenic at all.

SUMMARY

The important toxic reactions to Fowler's solution are discussed with particular reference to toxipathic hepatitis.

A case of hepatitis due to administration of Fowler's solution for dermatitis herpetiformis is described.

Treatment with dimercaprol resulted in the urinary excretion of considerable amounts of arsenic, with subjective and objective improvement, but diffuse fibrosis is likely to be the sequel to the administration of arsenic to this patient.

Fowler's solution should not be used without consideration of the risks, nor without careful clinical control.

We wish to express our thanks to Mr. Harri Heap, former city analyst for Manchester, for the considerable amount of work he so willingly undertook in carrying out the urinary analyses for arsenic, and to the Department of Medical Photography, Manchester Royal Infirmary, for the photographs.

POSTPARTUM ANAL FISSURE

J. D. Martin
M.D. Lond., M.R.C.O.G.
ASSISTANT, OBSTETRIC UNIT, UNIVERSITY COLLEGE OBSTETRIC HOSPITAL, LONDON

Anal fissure is common in pregnancy and the puerperium. Goodsall and Miles (1900) suggested that parturition causes overstretching of the anal mucosa, which is thus rendered more susceptible to trauma. Lynch (1914) and Smith (1939) noted that rupture of the perineum in childbirth predisposes to anal fissure. De Lee and Greenhill (1943) state that anal fissures are a common sequence to the stretching of the anus during labour.

MATERIAL

Many patients attending the postnatal clinic at this hospital six weeks after delivery complained of anal symptoms. An investigation was therefore started in which such patients were examined for abnormalities in the anal region. The patients studied attended the postnatal clinic between December, 1950, and May, 1951. Of 642 patients booked to return to this clinic six weeks after delivery 424 attended and were questioned.

RESULTS

Of the 424 patients questioned 50 (11·8%) complained of pain or bleeding or both on defæcation. The following lesions were discovered :

Anal fissure	45 cases (10·7 % of total cases seen)
Hæmorrhoids	3 cases
Thrombosed hæmorrhoids	2 cases

Many patients were found to have skin tags round the anal canal, but only the lesions responsible for the patients' symptoms are included.

These figures show that anal fissure is responsible for most of the symptoms, and that the patient's complaint of "having piles" should always be regarded with suspicion. She will almost certainly have a fissure.

SITES OF FISSURES

The fissures were sited as follows :

Single fissures		*Multiple fissures*	
Anterior ..	15	Anterior	26
Posterior ..	8	Posterior	24
Lateral	1	Lateral	3
Total ..	24 cases	Total	21 cases
(54 % of total cases of fissure)		(46 % of total cases of fissure)	

In this series 62% of the single fissures occurred anteriorly. Multiple fissures were found in 21 (47%) of the women with fissures. Anterior fissure is agreed to be more common in women, but the proportion of anterior fissures in women seen varies from 8% (Pennington 1923) to 40% (Bacon 1943); most writers favour the lower figure. Goodsall (1892) mentioned that in 8% of his female patients both anterior and posterior fissures were present. Multiple fissures are common after parturition : two fissures were seen in 12 cases, three in 7 cases, and four in 2 cases. Gabriel (1948) states that multiple fissures are only occasionally met with, and in a series of cases of fissure at the Mayo Clinic (Buie 1937) found that 0·1% were multiple. But multiple fissures are common after parturition: two fissures were seen in 12 cases, three in 7 cases, and four in 2 cases. It must be emphasised that the fissure is seldom large, and very careful inspection of the anal margin is necessary in suspected cases.

ONSET OF SYMPTOMS

All the patients were questioned about the onset of symptoms, and their answers gave the following figures :

Antenatal	.. ..	6 cases
Postpartum	0–4 days	11 cases
	5–9 days	2 cases
	10–14 days	17 cases
	15–40 days	9 cases

The patients were discharged home on the ninth or tenth day of the puerperium, and most of them noticed symptoms within a few days of returning home. Undoubtedly with one contrast medium does not necessarily indicate sensitivity to another, they think that the standard intravenous test is of doubtful value in assessing the liability to a severe reaction In all, 17 deaths after intravenous pyelography have been reported, these have all followed administration of diodone Considering the great number of examinations performed every year, the margin of safety is large

TUBERCULOSIS IN NEW YORK AND LONDON

BOTH in New York[1] and London[2] the half-century up to 1950 has been marked by reviews of changes in the tuberculosis situation The unsatisfactory hygienic conditions of the 19th century, with large outbreaks of acute epidemic diseases causing many deaths, led to great sanitary advances at the end of the century In New York between 1900 and 1950 the population increased from 3½ million to 8 million, largely as a result of immigration, in 1910 40% of the population were foreign-born The Manhattan area was already crowded at the beginning of the century, and its population has increased little In the London county area the population declined from 4½ million to less than 3½ million between 1913 and 1950, owing mainly to migration from the crowded central areas to the suburbs, the population of Greater London, including the dormitory zone, has increased during this period, though not to the same extent as in New York Such major movements of population must affect the age-structure of the population, and hence also the epidemiological picture of tuberculosis Migration occurs especially among young adults New York has grown by immigration of this group from Europe especially, while in London it is predominantly the young adults that are likely to be rehoused outside the county boundaries

In both areas the death-rate from tuberculosis fell greatly during the half-century—in New York by about 90% from 280 to 29 per 100,000 The rate in London in 1900 was lower (223 per 100,000), but had not fallen to the same extent by 1950, when it was 40 per 100,000 The two wars had a greater effect on tuberculosis mortality in London than in New York, in the second war the fall in this rate in New York was hardly checked, whereas in London the rate rose steeply Evacuation raised the London rate artificially, since "the tuberculous were evacuated to a much less extent than healthy persons" The death-rate has shown the greatest fall in childhood, and comparatively little improvement in old age The control of bovine tuberculosis—by eliminating tuberculosis in cattle in New York State, by pasteurisation in London—has played a large part in the reduction of childhood mortality

In London compulsory notification of cases of tuberculosis was started in 1911 in New York "registration" of cases has been carried out since 1894, but was not complete before 1910 Since then the annual notification-rate has declined in each city, but this decline is much less than that of mortality, and it was interrupted during the war periods in both New York and London

The New York report describes differences in tuberculosis mortality between various racial groups The unfavourable record of the coloured population in this respect is well known, but there are distinct and consistent differences between the white groups of European origin The lowest rate is in the "native born" group, but presumably this includes a large number of children and is not really comparable with the various "foreign-born" groups In 1920 the highest mortality-rates were in those born in Ireland and Scandinavia, the lowest in those (mostly Jews) born in Russia Similar relationships are evident in the figures for 1890 and 1930

These reports show that, while there are fundamental similarities in the tuberculosis records of New York and London, detailed comparisons are not justified because of differences in population structure as regards race and age The New York report is especially valuable in bringing together in tabular form all the available records concerning tuberculosis in the city Both reports show that considerable progress has been made in reducing tuberculosis mortality, especially in childhood and we may echo the final hope of the authors of the New York report that by the end of the century tuberculosis will be rare at any age

ELECTRO-ENCEPHALOGRAPHY FOR BOXERS

SUPPORTERS of boxing often point out that severe injuries may be inflicted in sports which are not so often challenged as being dangerous, but, as we have remarked,[1] one of the boxer's main aims is to disable his opponent The medical subcommittee of the British Boxing Board of Control has laid down the conditions for compulsory examination A professional boxer must be examined after he has taken a count or after a fight has been stopped for any reason, and if he loses four consecutive fights a representative of the board interviews him and his manager But clinical examination, however frequent, cannot prevent occasional fatalities, and once in a while a death, such as that of M Pratesi, of France, a few months ago, revives the discussion whether these precautions are adequate The B B B C seems to take the view that no other method has yet been proved superior, but one suggestion to which thought is being given is that periodical electro-encephalographic (E.E G) examinations should be made

This procedure has been adopted in Colorado[2] where it was decided that every professional boxer should have an E E G examination (*a*) once a year, (*b*) within two weeks of a knockout, and (*c*) frequently if his record was abnormal In all, 24 men have been studied An increased prevalence of dysrhythmia was found in 8 of them, and there was some indication that those who had been knocked out showed a greater disturbance than those who had not Older men had, on the whole, fewer disturbances than younger ones In 1 case where the E E G abnormality was progressive the boxer was suspended Busse and Silverman[2] conclude that compulsory periodic E E G examinations contribute to the safety of boxers

Many workers in this field would disagree, for it is by no means certain that changes reflected in the E.E.G would not be discovered clinically This doubt is especially great in cases of acute injury, but one exception is the subdural hæmatoma which, though clinically "silent," may produce focal or general E E G changes In the Colorado investigation overbreathing was carried out routinely, and sleep records were taken when possible but no mention is made of blood sugar levels, and the allowances made for age changes are not clear On the last point it might be argued that some, at least, of the abnormalities described could be due to maturation defects In Gibbs's[3] opinion a diffuse abnormality is of no diagnostic value in post traumatic cases He states that (*a*) focal abnormality suggests brain damage, but absence of focal abnormality does not exclude it, (*b*) if a general abnormality is present three to four months after a mild injury the chances are sixteen to one that this abnormality antedated the injury, and (*c*) in post-traumatic cases the E.E G may be normal in the presence of known brain damage (of 160 patients with normal E E G s 3 had neurological evidence of damage) But Busse and Silverman's series is too small to point conclusively ly 6 cases of fissure in the antenatal period are scribed, although this condition is probably more mmon, but I have not had access to all the antenatal tients. The diagnosis of fissure in these cases is rticularly important if pregnancy is not to become a isery.

The recognition of anal fissure in pregnant and puer-eral women is important. Improvement will come by e avoidance of constipation in the antenatal and ostnatal periods, by great care in the use of enema ringes and at rectal examinations, and by the avoidance f damage to the anal margin by tears or episiotomy. In me cases, however, a timely episiotomy will reduce the amage to the perineum and anal mucosa. All patients hould be questioned, before discharge from hospital, bout discomfort or bleeding on defæcation, especially f forceps have been used. Instructions should also be iven, before discharge from hospital, for the patients o report at once if rectal symptoms appear before they re due to attend the postnatal clinic.

SUMMARY

45 cases of anal fissure are described in 424 women ttending a postnatal clinic (incidence 10·7%).

Hæmorrhoids are rarely responsible for rectal symptoms ix weeks after delivery.

Multiple fissures are common and were seen in 21 cases 46%).

Anterior fissure occurred in 15 (62%) of 24 cases with single fissure.

The causes, prevention, and treatment of anal fissures are discussed.

I wish to thank Mr. O. V. Lloyd-Davies for his help and advice in the preparation of this paper.

GASTRIC MUCOPROTEIN AND INTRINSIC FACTOR

RESPONSE OF PERNICIOUS ANÆMIA TO ORAL VITAMIN B_{12} PLUS NORMAL GASTRIC JUICE TREATED WITH RECEPTOR-DESTROYING ENZYME

BARRIE P. MARMION* M.D. Lond.
HILDA J. GARDNER M.B. Adelaide
ERIC G. SAINT† M.D. Durh., M.R.A.C.P.
JOHN L. STUBBE‡ M.B. Melb.

From the Walter and Eliza Hall Institute of Medical Research and the Royal Melbourne Hospital, Melbourne, Australia

THE chemical nature of intrinsic factor has long been a baffling problem and it is of great interest that Jerzy Glass and his colleagues at the New York Hospital have recently claimed that Castle's hæmopoietic principle is associated, if not identical, with a gastric mucoprotein (Glass et al. 1952).

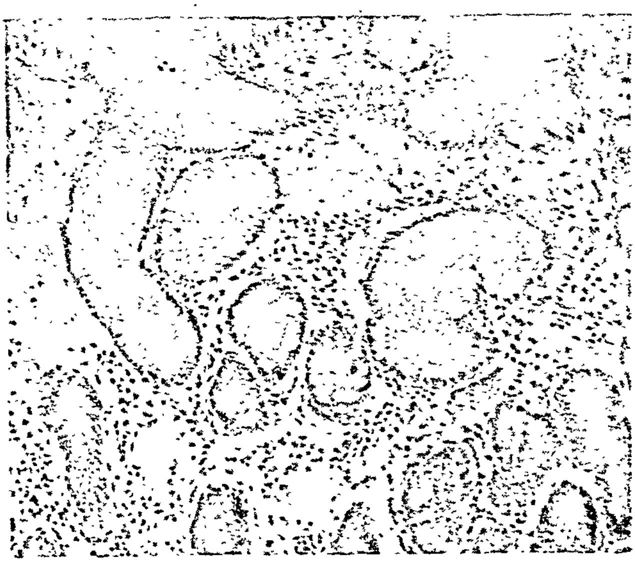

Fig. 1—Gastric biopsy showing mucosa reduced in width; surface epithelium partly columnar and partly goblet-cell in type, with pits leading to a few coiled tubules entirely composed of non-specific cells; infiltration of lamina propria with lymphocytes and plasma cells. Appearances are those of gastric atrophy characteristic of pernicious anæmia. (Hæmatoxylin and eosin. × 250.)

In 1947 Burnet and Stone discovered a soluble enzyme which was derived from *Vibrio choleræ* and could either modify or destroy the influenza-virus receptors on erythrocytes and on cells susceptible to experimental infection. A long series of investigations, reviewed by Burnet (1951), established that this receptor-destroying enzyme (R.D.E.) like that on the viruses themselves, was a mucinase acting on a considerable range of soluble mucins, including some of those present in egg-white, meconium, saliva, and human gastric contents. The chemical nature of the reaction is not yet established, but Gottschalk (1951) has provided evidence which points strongly to an action on the carbohydrate moiety of the mucoproteins in egg-white and urinary inhibitor. In addition to destroying the power of mucoproteins to react with influenza viruses the enzyme produces a sharp change to a less electronegative state in the electrophoretic mobility both of red cells and of soluble mucoproteins. Whitten (1949) reported the very interesting finding that R.D.E. could destroy the biological activity of the mucoprotein gonadotrophic hormone.

In view of this apparently specific action on a variety of mucoproteins it was of interest to see whether the gastric mucoprotein believed by Glass to be the intrinsic factor would lose its activity after treatment with R.D.E.

CASE-RECORD

A woman, aged 29, was admitted to the Royal Melbourne Hospital on May 12, 1952. She had been successfully treated with liver extract for "anæmia" in Yugoslavia in 1949 but had allowed her injections to lapse for eighteen months, she had become weak, tired, and breathless on exertion.

On examination she was very pale and slightly icteric. Her tongue showed moderate papillary atrophy. There was no evidence of subacute combined degeneration of the spinal cord.

Investigations revealed the classical features of pernicious anæmia. A histamine test-meal showed complete achlorhydria, and a gastric biopsy, obtained by the method described by Wood et al. (1949), showed atrophic mucosal changes typical of addisonian anæmia (fig. 1). A blood-count showed Hb 6·8 g. per 100 ml.; red cells 1,600,000 per c.mm.; white cells 6000 per c.mm.; packed-cell volume 30%; mean corpuscular volume 150 c.μ; mean corpuscular Hb 36 μμg.; mean corpuscular Hb concentration 26%. A blood smear showed considerable macrocytosis and variation in size of the red cells, with numerous poikilocytes. A sternal-a characteristic histological picture of swollen elastic tissue Electron microscopy showed that in fact there was no increase in elastic fibres in this condition, but that the collagen fibres were abnormally short it is these collagen fibres that take up the elastic stain On the other hand, not all abnormal collagen stains like elastic fibres In Werner's syndrome, where the electron microscopes shows grossly degraded collagen in the skin, histologically the elastic staining is normal

‡ Drug Houses of Australia Fellow.

The discrepancy between the results of histological staining and electron microscopy, and its convincing explanation by the Leeds workers, throws some light on the nature of the morphological changes in the skin with age It also underlines the inadequacy of staining techniques alone as a means of interpreting the morphology of connective-tissue lesions in general It is reasonable to hope that the simple technique of enzymatic digestion, used in conjunction with quantitative biochemical analysis and, where feasible, with electron microscopy, may give much help in the elucidation of connective tissue disease

SIGNS OF PAIN

Pain, being essentially subjective, is not easily assessed It has objective counterparts, such as wincing, reflex withdrawals, vocal expressions, sweating, and changes in respiration, heart-rate, and blood-pressure, for example, in association with ischæmic muscular pain Alam and Smirk[1] recorded increases in blood-pressure and heart-rate, and Thompson and Gellhorn[2] reduction in electrical skin resistance But such changes vary greatly from one person to another, and are slight or absent with mild or moderate pain, and in gauging the action of an analgesic drug it is important to remember that this drug may influence the accompaniments of pain by mechanisms unrelated to those which underlie its relief

Wolff et al[3] have distinguished between pain perception and the reaction pattern to pain The reaction pattern involves withdrawal, fear, flight, or anxiety and is associated with visceral reactions such as those already mentioned Its association with pain is extremely variable, indeed the reaction pattern may be induced by mere apprehension of pain, as when sitting in a dentist's chair The most important way in which morphine relieves pain is by preventing the usual reaction pattern, even though pain is still perceived and recognised as such Thus analgesic drugs are best judged by recording the patient's own words, and the reliability of this evidence can be tested by careful control of the nature and doses of the drugs given[4]

Dr Phyllis Croft[5] has reported on the reflex tachycardia from painful stimuli in rabbits and in man She suggests that the "cardiac pain reflex is a reliable and convenient method of assessing pain perception . particularly useful in conditions of curarization" Here the "cardiac pain reflex" does not mean, as one might suppose, that pain arises in the heart, but that the heart-rate responds by an increase when a nocuous stimulus is applied to the skin Furthermore, the word "perception" should mean awareness of something and has no meaning when a person is unconscious In the second stage of anæsthesia the patient is unconscious and unaware of pain, yet his heart-rate and blood-pressure may be increased by nocuous stimuli Dr Croft has sought to correlate in rabbits and in man the electrical changes in the brain with pain perception Much might be learnt from such observations, but only by making them in man Conditions in which animals *feel* pain cannot be determined except by extrapolation from human experience Sherrington,[6] discussing reactions to harmful stimuli in animals, said "In all this experimental work on animals the observer has to work through signs of subjective states incomparably inferior in most instances to the verbal communication establishable with an intelligent human being", and Lewis[7] observed that "We have no knowledge of pain beyond that derived from human experience" This of course means, not that animals do not suffer when they show the behaviour characteristic of human beings in pain, but that in this field man is the measure of all things

COLD CARDIAC SURGERY

Although many uses have been suggested for general or regional refrigeration in clinical medicine, the results have been disappointing[8] "Hypothermia," however, has recently aroused the interest and ingenuity of the experimental surgeon Bigelow and his colleagues,[9] for example, have demonstrated experimentally the way in which cooling of the patient's body may the cardiac surgeon When the body-temperature dogs was reduced to 20°C (68°F), the cardiac inflow could be interrupted for long enough to permit the heart to be opened and its interior examined Delorme described how cooling of the blood-stream seemed to be practicable method of lowering the respiratory activity of the cell without endangering life He found that dogs whose body-temperature had been reduced to 25 (77°F) were able to survive long continued reduction in blood volume, as well as suspension of blood flow Lewis and Taufic[8] have now reported that they could make, and subsequently close, atrial septal defects under direct vision in hypothermic dogs 27 out of 29 dogs survived the operation for production of the lesion and these defects were successfully closed later in out of 26 of these animals These experimental findings have been excitingly translated into clinical reality using the same technique as in dogs Lewis and Taufic have successfully operated on a five year old girl with an atrial septal defect She was anæsthetised and wrapped in refrigerated blankets until, after two hours and minutes, her rectal temperature had fallen to 28 (82 4°F) The blankets were then removed and the operation began The cardiac inflow was occluded for 5½ minutes, and a 2 cm septal defect was closed under direct vision The operation lasted 58 minutes and the patient's rectal temperature after this time was 26 (78 8°F) She was restored by immersion in hot water at 45°C (113°F), and after 35 minutes her rectal temperature had risen to 36°C (96 8°F), when she was removed from the bath She did well after the operation, and left hospital 11 days later The cardiac murmur had gone

This technique has all the makings of a major advance in cardiac surgery But Lewis and Taufic observed ventricular fibrillation in some of their dogs after operation, and this possibility, and doubtless others, will need careful consideration

---

The executive board of W H O met in Geneva on Jan 27 to nominate a successor to Dr Brock Chisholm director-general of the organisation, whose term of office expires on July 21 They chose Dr Marcolino Gomes Candau, of Brazil, who is at present assistant director of the Pan-American Sanitary Bureau in Washington The nomination will be put before the sixth World Health Assembly which opens in Geneva on May 5

Medical Societies

ROYAL SOCIETY OF MEDICINE

nction of the Hospital Outpatient Department

THE sections of medicine and of general practice of e Royal Society of Medicine met together on Jan. 27, der the chairmanship of Dr. E. P. SCOTT, to discuss e Function of the Hospital Outpatient Department.

Sir JAMES SPENCE pointed out that the outpatient partment was a place of many functions. The general actitioner referred patients to hospital for consultative vice or specialist examination, sometimes only to get l of a troublesome person or because the patient asked for What the hospital offered might be a true consultation a clinical display for students, together with specialist chnical examinations of eyes, ears, &c., a casual- eatment department, and follow-up clinics. It was a eting-ground not only of patient and doctor but also students, nurses, almoners, and clerks, who all had eir different views of it. The department was usually the hospital cellars, lined with lavatory tiles, lodged e a poor relation in the space which could not be used r wards. He thought it a great pity that in the com- tition between the dispensaries and infirmaries in the th and early 19th centuries the infirmaries had won. aving captured the outpatient work the hospitals had en made it subsidiary to inpatient care, fitting it into amped quarters and appointing junior men to do it. many provincial suburban practitioners today had ill- uipped and unsuitable surgeries it was partly because ey had copied what they had seen as students in the tpatient departments of their teaching hospitals. In e present time of rapid change it was important to ink out what such a department should be, instead of ontinuing blindly along the old beaten track. Let us ttle the priorities, make some experiments, and try to ut improvements into practice.

Sir James said he believed that, above all, the outpatient epartment should offer a true consultation on the lines f private practice. General practitioner and consultant hould be personally acquainted. and the patient should e fully introduced by a telephone conversation between hem. Failing that, a good letter should be sent. Best f all was if the practitioner could attend with his patient. he consultation must be completely private—just the onsultant with the patient and his own doctor—and no urses, almoners, or clerks should be allowed in the room. n teaching hospitals a maximum of two students might ssist the consultant, with the patient's permission, which would be given in 90% of cases. But there should be no linical teaching except between cases. Students had lenty of other opportunities to learn physical signs nd pathology. What they could gain only from the utpatient clinic was the example of an experienced erson handling a human situation, making not only a medical diagnosis but an estimate of the patient's view f his own illness, and the level on which explanation and advice could best be offered to him. The purpose of a consultation was to explain to, and advise, the patient as well as his general practitioner. Sir James said that when after a consultation fraught with emotion he saw the captain of the university football team wiping a tear from his eye he knew that it had been valuable to this student as well as the patient.

Dr. R. J. F. H. PINSENT gave a general practitioner's view, by which a hospital visit was only an incident in his patient's medical life. He chose his consultants by the kind of reports they sent back, and tried to get to know those he approved of. In one year he had 2176 first attendances at his surgery, and referred 412—nearly a fifth—to a hospital. About 60 of these patients were referred to the casualty department, which was better equipped than he for minor operations. Medical, surgical, and ear, nose, and throat clinics each received over 11%, while 9% saw the dermatologist. Some of these cases were for diagnosis, others for special investigation, radiography, or physiotherapy. He arranged consultations by telephoning the hospital's appointments bureau, which was, however, shut at the time of his evening surgery. But the real trouble was the delay in getting reports back afterwards. He instanced a young man with a presumed peptic ulcer for whom on Oct. 29 he arranged an outpatient appointment. The consultant saw the man on Nov. 3 and ordered a barium meal. Radiographs were taken on Jan. 7, but no report on them was forthcoming by Jan. 27. Meanwhile the patient, who called at his surgery regularly for news, was looking better. He had bought a book on the cure of ulcer at a railway bookstall and was treating himself, apparently with good results. Hospitals ought to send out letters and reports the same or the next day, on paper of a standard size for easy filing.

There were too few clinical assistantships for general practitioners; no form of postgraduate education did them more good. They ought to be always welcome as visitors to the outpatient department in any case, with or without their patients, so that it became a common ground where consultant and practitioner met and combined specialised knowledge with human understanding. The practitioner might thus also be brought into schemes of research. Another link could be formed by inviting hospital registrars to visit evening surgeries—valuable experience for them now that a would-be consultant could no longer begin his career in general practice. But though the outpatient department should become a medical centre for the district, it should not absorb the personal health services run by local authorities. Preventive medicine lay in the general practitioner's sphere.

Brigadier G. P. HARDY-ROBERTS said that the hospital administrator's job was to try to keep everyone happy; but this was only possible if doctors appreciated the administrative difficulties. General practitioners sometimes sent patients without mentioning which consultant's advice (or even which clinic) they wanted, or the relative urgency of the case. Consultants were sometimes unpunctual or absent without warning. They ought to indicate to lay staff what bookings they wanted, and it was good if they could develop a "waiting-room consciousness." Marshalling the patients was work for porters, and for educated girls who must be taught that smiling and lack of shyness were part of their job; providing these girls with white coats helped this; and porters were more efficient if given good uniforms and ordered to polish their buttons. Documentation was humbler work, for less intelligent girls. Nurses must be kept for nursing duties. Periodical staff conferences with representatives of each of these three divisions and of the consultants and registrars helped to smooth out difficulties. It would be very valuable if these conferences could also be attended by a representative of the general practitioners who used the hospital.

From the general discussion several important points emerged. If more outpatients are to be seen, as modern conditions require, the consultant must accept responsibility for running his clinic. At the same time some of the patients, particularly some of the elderly, referred to the medical outpatient department do not really want to see a doctor, but benefit from attending a social club organised by the outpatient department; and this saves the consultant's time. Apparently not every clinic separates old from new cases, nor is it yet clear to all that a case may be urgent for economic as well as medical reasons. Organisation varies a good deal from hospital to hospital, and the best practices should be more widely known and imitated.

seen † Prior to the start of prophylaxis, beta hæmolytic streptococci should be eradicated by proper treatment of the patient (See methods of penicillin therapy recommended above)

How Long Should Prophylaxis be Continued ?

In children, at least to the age of eighteen , in all those above this age, for at least five years from their last attack

Should Prophylaxis be Continued During the Summer ?

Yes

PROPHYLACTIC METHODS

Sulphadiazine

This drug has the advantage of being easy to administer, inexpensive, and effective (other newer sulphonamides are probably equally effective) Although resistant streptococci have appeared during mass prophylaxis in the armed forces, this is rare in civilian populations.

Dosage —From 0 5 to 1 0 g taken each morning throughout the year The smaller dose is to be used in children under sixty pounds

Toxic reactions —These are infrequent and are usually minor However, in any patient being given prophylaxis with sulphonamides consider all rashes and sore throats as possible toxic reactions to the drug, especially if they occur in the first eight weeks of prophylaxis The chief toxic reactions are .

Skin eruptions

(*a*) Morbilliform, much like measles Continue drug with caution

(*b*) Urticarial Best discontinue treatment

(*c*) Scarlatiniform, often associated with sore throat and fever Unsafe to continue drug

Blood reactions .

Leucopenia Discontinue if white blood count falls below 4000 and polynuclear neutrophils below 35% because of possible agranulocytosis which is often associated with sore throat and a rash Because of these reactions, weekly white blood counts are advisable for the first two months of prophylaxis (The use of sulphonamides therapeutically for any reason in this period should be preceded by a white blood-count) The occurrence of agranulocytosis after eight weeks of continuous prophylaxis with sulphonamides is extremely rare

Penicillin

Although experience with oral penicillin for the prophylaxis of rheumatic fever is more limited than that with the sulphonamides, the antibiotic promises to be a safe and effective prophylactic agent Oral penicillin has the desirable characteristics of being bactericidal for hæmolytic streptococci and of rarely producing serious toxic reactions It has the disadvantages of being more costly than sulphadiazine and because of the need of giving it on an empty stomach, of being somewhat more difficult to administer Oral penicillin represents an alternative drug for rheumatic fever prophylaxis It is especially important to use this agent for those who do not tolerate sulphadiazine

Dosage —Although other routines of administration may prove satisfactory, the following schedules are suggested *200,000 to 250,000 units two times daily is recommended* Since penicillin is best absorbed on an empty stomach, the time of administration should be 1/2 to 1 hour before a meal or at bedtime A single dose of 200,000 to 250,000 units before breakfast is less preferable

Toxic reactions —(1) Urticaria (2) Reactions similar to serum sickness—they include fever and joint pains and may be mistaken for rheumatic fever (3) Angioneurotic œdema Although many individuals who have had reactions to penicillin can subsequently take the drug without trouble, it is safer not to use penicillin, if the reaction has been severe and particularly if angioneurotic œdema has occurred

TEACHING OF SOCIAL AND MEDICINE

THE Royal College of Physicians, through its and Preventive Medicine Committee, has been ing methods of teaching social and preventive me and comparing present conditions with those describ in the committee's first interim report of 1943[1] The progress report published last month observes that chairs of social or preventive medicine have now been created in almost every provincial university, thus going towards fulfilling the committee's earlier hope that every medical school would eventually have a department of social and preventive medicine

PROVINCIAL SCHOOLS

Turning first to the provincial medical schools, the committee found that almost everywhere the number of hours' teaching directly devoted to social medicine had been doubled , and in general the curriculum in social medicine is spread over the three clinical years Some departments are directed by a whole-time professor who has one or more active medical officers of health on his staff , others are directed by a medical officer of health as part-time professor or lecturer, with whole-time university lecturers carrying out most of the teaching programme There is remarkably little difference between the two arrangements, the report continues, and one way or the other "the programmes of the different provincial schools show an encouraging improvement," although "a detailed examination suggests that in some of them there are still serious gaps in teaching practice. The importance of occupational health and industrial medicine is generally accepted, but some schools are unable to give these subjects as much teaching time as they would wish Personal hygiene and environmental hygiene have a place in the undergraduate curriculum of every provincial school, but the amount of time devoted to them is relatively small The report commends the statistical departments which are appearing within, or in close association with, some departments of social medicine

> "Theoretical statistics is a subject often included in the social medicine curriculum, but more as a matter of convenience than on grounds of compelling logic As a rule, however there is no alternative provision for teaching this subject and in the absence of a separate Statistical Department the attachment of a Statistical Section to a Department of Social Medicine is usually a good working arrangement"

LONDON SCHOOLS

The arrangements in London are very different partly because the schools do not have to give postgraduate teaching in public health, which is provided by the London School of Hygiene and Tropical Medicine and by the Royal Institute of Public Health Apart from courses of formal lectures for undergraduates, the London schools aim to teach by integrating social aspects of illness with clinical subjects and pathology The report quotes the dean of one London school "Social medicine cannot and should not be taught to the undergraduate student as a special subject" It seems that the undergraduate schools in London are undertaking social medical research in the way that many of the provincial schools are doing The committee conclude "it appears that generally speaking the consolidation of social medicine as a subject in the curriculum in London lags behind the best provincial arrangements Epidemiology in the wide sense does not appear to be treated systematically at any point in many London schools"

---

† In patients receiving A C T H or cortisone be cautious that other infections are not masked since the prophylactic dose is inadequate to treat such concurrent illnesses as pneumonia or meningitis

THE LANCET

LONDON: SATURDAY, FEB. 7, 1953

Outpatients

LOOKING at the country as a whole, the state of tpatient departments is unsatisfactory both to tients and to doctors. The reasons are not hard to d. In the old days the care of inpatients had first iim on the limited resources of voluntary hospitals, d consequently the outpatient department was ten cramped and sometimes badly placed in some rt of the hospital, such as the basement, which uld not conveniently be used for other purposes. w of the municipal hospitals had developed any itpatient services at all, and the pressure thus rown on neighbouring voluntary hospitals was often ry heavy and quite out of proportion to their imber of beds. Before the war, many hospitals iver caught up with local expansions of population— the heyday of pre-war building, Middlesex county as expanding at the rate of 1000 people a week— id the failure to provide sufficiently for new demands the cause of some of our present difficulties. (Even iday, when we build new towns we do not build new ospitals to serve them.) Since the war many hospitals, pecially in Greater London, have been faced with a rowing demand for outpatient facilities, but have een severely restricted in any kind of new conruction. It is hardly surprising, therefore, that a eneral dissatisfaction with existing arrangements for utpatients should have been evident when these were iscussed at the Royal Society of Medicine's meeting hich we report on p. 275.

The functions fulfilled by an outpatient department re various and sometimes numerous. They provide he patient and his doctor with the opinion of a onsultant; they enable special diagnostic investiations to be made; they may accommodate services uch as eye-testing; they may include supervisory linics for patients with particular diseases such as næmia or diabetes, and for those whose progress ifter treatment, is being watched; and in some iospitals they are of course used for teaching. Their most important service to the community is probably the provision of a second opinion, which should be based on a careful history and thorough examination, with necessary investigations, followed by adequate discussion with the patient. Some would say that transmission of the results of the various investigations to the patient's doctor, and the application of a diagnostic label, are of less moment than the reassurance and help the patient will get from a proper consultation. But unfortunately, with excessive pressure on outpatient departments, the patient-consultant relationship is bound to become impersonal, and what is perhaps the most valuable function is not properly performed. In the eyes of the public, for whom the National Health Service has been organised, delay in securing an appointment is another grave defect. Before the war, outpatients often had to wait some hours before they were seen; but at least their initial attendance was not postponed for some weeks, as all too often happens under the system by which patients are given appointments for particular dates.

At the Royal Society of Medicine, Sir JAMES SPENCE laid stress on the need that outpatient departments should provide a true consultative service, and he laid down conditions under which this could be achieved. The patient, he said, should be properly introduced by letter or telephone; a specific appointment should be arranged; the history should be taken privately without a nurse in attendance; and at a teaching centre not more than two students should be present, and then only with the patient's consent. No teaching should be done in the presence of the patient, who should have the consultant's undivided attention. The consultant must not be content with making a diagnosis, but must explain and discuss the malady in terms that the patient clearly understands, carefully eradicating any misconceptions the patient may have formed. And finally a prompt report must be sent to the general practitioner. To some of Sir JAMES's hearers, who do their work in crowded outpatient departments where fifty or more patients attend in one session, some of these conditions must have seemed hopelessly unattainable. But even if the ideal consultation cannot be achieved at present, its acceptance in principle would be a sound basis for much-needed reorganisation in hospitals, and also perhaps a contribution towards improving conditions of general practice. Sir JAMES SPENCE believes that radical improvement in the outpatient departments of teaching hospitals is essential if we are to give medical students satisfactory standards. He thinks that the inadequacy of the consulting-rooms to be found in many practices is related to the inadequacy of the accommodation for outpatients at the hospitals where the practitioners were taught.

Even without new buildings many outpatient arrangements could be appreciably improved by careful reorganisation and attention to detail. In working appointment systems, which have been usefully studied by investigators of the Nuffield Provincial Hospitals Trust,[1] it is important to separate old and new patients, and the consultant should accept some responsibility for timing in his particular clinic. The number of appointments should be carefully related to the number of doctors working in the department, and unnecessary work should be eliminated by returning patients to their own doctor as soon as possible. (Many of the less senior members of hospital staffs probably have no idea how greatly many practitioners resent having patients removed by the hospital from their immediate care, when they have asked only for some diagnostic procedure.) The division of administrative responsibility between the hospital secretary, records officer, outpatient sister, and medical staff has often hindered necessary changes in routine, and, though the responsibility is essentially a medical one, the medical staff may properly organise a subcommittee, coöpting others who may be concerned. These should include a local practitioner, whose point of view may be invaluable, and who can speak from experience of, for example, the advantage of having reports written on notepaper that fits easily into the National Health Service envelope. The hospital secretary, if he takes a keen personal interest, can do much to promote the smooth running of out-

DISCUSSION

The stage of pregnancy at which pulmonary tuberculosis is first diagnosed materially affects the prognosis, and McIntyre and Armstrong (1948) have shown the high mortality among patients first found to have active pulmonary lesions in late pregnancy and in the puerperium Clearly, a higher proportion can be diagnosed by radiology than by clinical examination alone The medical officer of health for Glasgow (1949) reports that tuberculosis is the commonest cause of death in Glasgow children under the age of 5, and now that B C G inoculation is becoming more widely used, the importance of detecting all cases of tuberculosis is greater than ever

Routine Wassermann tests are performed in all antenatal clinics, and Eisele et al (1942) found a positive W R in 0 87% of the women in their complete series This figure is much the same as the proportion of tuberculous chests discovered by X-ray examination, which varies between 1 2% and 3 0%, with active lesions present in 0 6 to 1 1% It must be remembered that *in the present series of 29 cases, tuberculosis had been* diagnosed before pregnancy in only 1 case

Few antenatal clinics undertake routine X-ray examination of the chest The disadvantage of the straight X-ray film is the expense, each film costs approximately 6*s*, and with a discovery rate of about 2 5% the cost per positive film would be £6, which is out of the question at the moment Moreover, the present shortage of X-ray film makes this form of investigation impossible in this country.

Alternative methods of diagnosis are tuberculin testing, screening, and mass or miniature radiography Tuberculin testing seems cumbersome and involves several visits for the patients In the series described by Ianne and Muir (1939) 14% of the women failed to return for the reaction to be read, and 11% of the reactors did not return for radiography Moreover, since 41–47% were positive and required X-ray examination, the total expense is little less than that of a survey using X-ray films from the start

Screening was used by both Eisele et al and Jacobs (1946), and both seem to have found it satisfactory Films were taken for permanent record in positive and suspicious cases Israel and Hetherington (1941) stated that the accuracy of diagnosis by fluoroscopy was as high as 96–99%

Eisele et al said that mass radiography probably sacrificed accuracy to a point where it was equal to or below that of fluoroscopy However, the method is being used for antenatal patients in some areas, and further reports would be valuable Miniature radiography is also reported to be relatively cheap and accurate

Screening or mass or miniature radiography seem feasible methods Certainly, the claims of the antenatal patient must be considered in allocating our limited radiological facilities The welfare of mother and child may ultimately rest on the antenatal chest examination of the mother, and, since a high proportion of tuberculous lesions escape detection by any other means, routine X ray examination of all antenatal patients is the ideal at which to aim

SUMMARY

Routine X-ray examination of the chest in 541 unselected antenatal patients showed evidence of tuberculosis in 29 cases (5 3%), and in 4 (0 74%) of these patients the disease was definitely active Another 8 patients had inactive disease, but after confinement 2 of them showed definite activity and 2 possible activity Of the remainder, 4 patients had healed fibrotic lesions and 12 had calcified pulmonary lesions In only 1 of these cases was tuberculosis known to be present before the radiological examination

A high proportion (94%) of the women who were asked to attend for X-ray examination did so

The early diagnosis of tuberculosis is particularly vital in pregnancy, and disease discovered in late pregnancy and in the puerperium has a relatively high mortality One of the various radiological methods of diagnosing pulmonary tuberculosis should be used as a routine antenatal measure

I wish to thank Dr Hugh Stirling, obstetrician in charge, for his advice, and Dr J Z Walker, director of radiology, and his staff for their help

Deaths during the Fog

More details about the effects of the thick fog which covered many parts of the country from Dec 5 to 9 are given by Dr J A Scott, medical officer of health to the London County Council, in a report to the council's public-health committee In the week ended Dec 13, 1952, 2484 deaths were registered in the administrative county of London, the figures for the preceding three weeks were 753, 853, and 945, and for the following three weeks 1523, 1029, and 1372 (the apparent drop to 1029 was due to the usual delay in registration at Christmas Dr Scott compares the number of deaths in the week of the fog with the figures for other weeks during the cholera epidemic of 1866, the great fog of 1873, and the influenza epidemic of 1918

Week ending	*Aug 4, 1866 (cholera)*	*Dec 20, 1873 (fog)*	*Nov 9, 1918 (influenza)*	*Dec 1 19*
Deaths registered (per million population)	876	713	1085	713
Normal number of deaths for period and season (per million population)	150	470	300	30
Excess of deaths over normal	126	213	785	443

Though the death-rates in the two fogs were much the same, the increase in 1952 was considerably greater because of the fall in the normal winter death-rate since 1873 The increase is greater than that in the worst week of the cholera epidemic

An analysis of all the deaths registered in the County of London between Nov 15 and Dec 27 shows that the increase was more pronounced among babies and old people, but all ages were affected The causes of the increase were almost entirely deaths due to circulatory or respiratory diseases in the week ended Dec 13 there were 10 times as many deaths from bronchitis as would have been expected from the preceding three weeks' figures, and on this basis deaths from influenza increased sevenfold, from pneumonia nearly fivefold, and from pulmonary tuberculosis over fourfold

DAILY ATMOSPHERIC SMOKE AND SULPHUR DIOXIDE AVERAGES AT COUNTY HALL LONDON S E 1

Day	Smoke (mg per c m)	Sulphur dioxide (parts per million by volume)
Dec 3	0 61	0 220
4	0 49	0 111
5	2 64	0 751
6	1 15	0 855
7	1 46	1 339
8	1 46	1 339
9	1 22	0 472
10	1 22	0 472
11	0 32	0 221

Smoke is expressed as mg of black suspended matter per cubic metre of air The figures for Dec 7 and 8 and Dec 9 and 10 are averages for the 48 hours stly method and the drug has to be given on an mpty stomach. Serious toxic reactions, however, e rare. Until lately parenteral penicillin has not een thought feasible for such long periods of rophylaxis, but the recent introduction of a particu-rly long-acting preparation (N,N′-dibenzylethylene-amine dipenicillin G) brings penicillin prophylaxis ithin the bounds of practicability. This drug enzethacil or 'Bicillin') has no significant toxicity, nd has the advantage of being very sparingly soluble ts solubility in water is equivalent to about 200 units f penicillin per ml.). FLETCHER and KNAPPETT[5] ave now investigated the use of this compound, and TOLLERMAN and RUSOFF[6] in New York have eported a trial of its use as a prophylactic in heumatic children in hospital. Both investigations how that it is possible to maintain low serum levels f penicillin continuously in an encouragingly high roportion of individuals by means of simple intramuscular doses spaced at intervals of as long as a ortnight. The serum levels attained are variable, nd may be very low or even intermittent. It is ossible that this might favour both the emergence f resistant strains and the development of drug ypersensitivity; but neither of these troubles has o far proved to be a serious complication. In the American trial, the value of the drug as a prophylactic against rheumatic recurrences was not established, or although none occurred, there was only one recurrence in untreated patients in the same hospital during the period of the trial. Further experience is therefore required to estimate its value in prophylaxis. But it might be hard to justify a trial of this kind in Great Britain, where it is widely believed that recurrences of rheumatic fever are quite uncommon—an opinion that cannot be challenged without extensive follow-up data. At all events, it is well to remember, in the light of the American Heart Association's statement, that there are gaps in our knowledge of the natural history of rheumatic fever in this country.

Law and Public Feeling

LAWS are at best rules of thumb, designed to do, under average conditions, the "greatest good to the greatest number." There will always be some criminal cases where the outcome leaves the public conscience uneasy. Is it logical to hold an adolescent fully responsible for his actions at 18 but not at 17? Naturally not. Many factors influence his stage of maturity, including his genetic endowment, his endocrine development, his education and training, his emotional experiences, and his own choices. Yet the law must rule a line somewhere, and declare that roughly speaking most people are responsible for what they do at and after such and such an age; and until we encounter a case such as that of Bentley and Craig we are prepared to accept that this should be so. When the margin is narrowed, however—when a young man of 19 is sentenced to death for inciting another, in a moment of violent excitement, to shoot—we are obliged to ask ourselves whether in holding to the letter of justice we are letting the spirit escape. The issue of the *Times* which announced the execution of Bentley also carried a report of two boys at Trowbridge who have been stealing from safes and churches, who have used stolen money to buy firearms, knives, and a tent, and who resisted arrest, striking the police officer in the face and abdomen. Their ages are 16 and 14, and they have been sent for three years to an approved school, where they will have a 3 to 1 or 4 to 1 chance of reform. The discrepancy between their punishment and that of Bentley (whose offence was of the same order though of greater degree) seems startlingly wide. Against these considerations we have to set another: we are properly proud that our police do not ordinarily carry firearms, and if we ask them to face the risks this entails we must stand by them fully when such arms are used against them. It is generally held that the only way to do this is to deal severely with anyone who attacks them, and that in such cases the prerogative of mercy should not be exercised. According to law and practice, therefore, Bentley was justly hanged. If we think that nevertheless justice was not done, then we do not like the law or the practice. There is an 18th-century record of a boy of 11 who was justly hanged for a small theft. We have since found that law both intolerable and unnecessary.

These perhaps are not directly medical concerns; but the psychological atmosphere evoked by the recent execution certainly is. What are the motives which bring five hundred people to the gates of a prison where a man is being hanged? What lies behind the public emotion which this case has excited? Does such an experience do people good or harm? Answers to these questions must be largely guesswork, but there are some small pieces of evidence on which to base a guess. The *Manchester Guardian* correspondent who watched the scene at Wandsworth saw, among those present, members of an association formed for the abolition of capital punishment, who sang a hymn and a psalm; a woman who had lived in the same street as Bentley; a man who had attended the last fifteen such occasions, who said "Nice fresh June morning and a little more sun, that's what you want really"; and four people who had taken a taxi from Birmingham in order to be there. Thus this relatively small crowd contained representatives of the types who used to flock to public hangings and burnings: those who used the event to protest against the law as it stood, and who tried to bring the condemned man some message of religion; those who derived a *frisson* from a macabre occasion; those whose idle curiosity was not bridled by any sense of embarrassment; and no doubt others who came to see what it was like, or because a friend had brought them, or because they thought it could not really happen, or because they were passing at the time and saw the crowd, or because they thought we had grown a lot too soft with criminals and things needed tightening up. None of these motives—except the first and the last, which can be defended by argument at an intellectual level—deserves respect; and it was because the country as a whole did not respect them that public executions were given up. Nevertheless it is clear that the same motives still operate, and would doubtless be manifest on a much larger scale if sanctioned and encouraged by public opinion. Restitution of public executions would suffice to restore the audiences.

exercised undue influence, they should not let the fact that he was a doctor weigh with them but should come out boldly and find him guilty of the coercion Medical practitioners may wonder how long it has been since juries have shown themselves especially tender towards doctors The plaintiff in the recent litigation is to be congratulated on the jury's view of his conduct As, however, the court ordered all costs to be paid out of the estate, and as the trial had occupied six learned counsel for nine days, it may be that the deceased's estate of some £22,000 will suffer serious erosion

Occasional Survey

URTICARIA

SCIENTIFIC terms, like currency, are subject to "inflationary trends" overusage may debase a respectable term until it is almost meaningless Moreover, the circulation of pseudoscientific counterfeits throws suspicion even on the original legal tender, so that those who wish to speak and write precisely shrink from using such terms This fate has befallen "allergy," a word introduced in 1906 by von Pirquet [1] Its meaning should be confined to specific and acquired changes in the capacity of the body to react after exposure to living or inanimate agents But it has come to be used often for non-specific changes in the intensity of this reaction, or as if it were synonymous with hypersensitivity Allergy includes diminished or absent reactions as well as excessive ones, it is the opposite, not of "hypoergy," but of "normergy" Allergy is essentially an immunological process, and may affect the whole organism or only a part—for example, the skin in urticaria

THE MECHANISM OF URTICARIA

But urticaria, the skin's defence against threats to its vascular endothelium, is not necessarily an allergic manifestation The sting of a nettle contains histamine and acetylcholine [2] and so invariably causes wealing But this is not allergy, nor is bronchospasm caused by a gaseous or particulate irritant, nor the sneezing and nasal congestion induced by pepper These are normal, temporary, localised, and protective reactions by the organism to a particular threat Acetylcholine, codeine, morphine, and atropine have a histamine like action and also release histamine, so that urticaria caused by these drugs is at most only partly allergic [3]

In some people a drug or food may cause urticaria, usually acute or subacute, possibly recurrent, and related to antigen antibody reactions and the release of histamine Heat, light, cold, and mechanical stimuli may cause lesions indistinguishable from those produced by antigen-antibody reactions, and it is probable that these forms are brought about by a chemical agent, possibly acetylcholine In particular, urticaria caused by heat, exercise, or emotion has been linked, by Grant et al [4] and by Hopkins,[5] with acetylcholine, probably released by the parasympathetic system

In chronic or recurrent urticaria the most careful search usually fails to reveal an antigenic cause The severe subcutaneous variety known as "giant urticaria" is, as the name "angioneurotic œdema" implies, traditionally regarded as a neurotic condition The importance of emotional changes in the production of urticaria was emphasised by Stokes et al,[6] who thought that such disturbances were solely responsible for 12% of urticaria in their series, and partly responsible for 83% Various terms, such as "psycho-allergy," "allergy to life," and "emotional anaphylaxis" have been coined for these phenomena If there is a specific alteration in the reaction of these patients, it is not an immunological response to a specific antigen but rather a regression to an habitual morbid emotional pattern of feeling towards persons or events Roessle [7] suggested the term "pathergy" to cover a non-specific broadening of the basis of reaction These forms of urticaria are not related to the allergic varieties unless the colloquial meaning of allergy is accepted, and unless resentment at the protein of another human is taken as a manifestation of allergy Urticaria caused by such an emotion is "pathergic", and a wider use of this term might disperse a lot of the fog which obscures the meaning of the word allergy If there is such a thing as an urticarial personality it is not immediately obvious, for the wealing is linked with morbid fantasies not readily discovered by direct questioning, but only revealed by the spontaneous and unprompted choice of expression made by the patient in describing significant events

The regional defence mechanisms of lining membranes and the skin are, in the normal (normergic) individual, temporary emergency measures to deal with powerful irritants The pathergic individual uses them to deal with relatively trivial stimuli and for more persistent long-term needs He has acquired the habit of reacting to danger passively and in the same way as to regional assault Love, anger, or fear, if frustrated, are converted to longing, hate, and passivity, and the regional type of reaction is sustained This autonomic cholinergic form of urticaria is engendered from the archipallium, whereas the antigenic histamine form arises in the skin itself Feelings of helpless and passive resentment, often with masochistic fantasies, seem to be directly related to the outbreaks The retreat into fantasy is a feeble substitute for an advance into action or words Subsequent events which recall the earlier emotion laden situation may cause relapses The acetylcholine released acts on the arterioles whereas histamine acts on the capillaries, possibly explaining the larger subcutaneous lesions of giant urticaria

Graham and Wolf [8] say that a dilated capillary is, ipso facto, a more permeable one, and they produce evidence to show that arteriolar dilatation alone, without the intervention of histamine, may cause urticaria Trauma, even the pressure of clothing, may then by histamine release further lower the threshold of wealing and so localise the eruption to certain areas Graham and Wolf describe a correlation between the discussion of emotional episodes and outbreaks of urticaria Intense resentment about events to which the individual felt, for one reason or another, incapable of reacting in a positive way was the common starting point

Sometimes an urticaria apparently caused by an antigenic food or drug is in fact precipitated by a mental association with some emotional event which coincided with the first time the food or drug was taken In these circumstances, the food or drug is a specific mental, but not antigenic, precipitant

Fatigue also contributes to the production of urticaria, for it lowers the threshold of wealing Overwork, infection, or malnutrition may be significant, but it is the tiring effects of unsettled emotional conflicts that may particularly disturb autonomic function and increase the sensitivity of the individual's reactions to antigens and events alike, so that hyperergy, the commonest form of allergy, results Adrenaline depletion and failure to remove histamine may well be part of the mechanism by which this allergy develops Rose and fertile eggs. They found that similar recombinants ıld be recovered from chick brains after inoculation MEL and NWS on to the chlorio-allantois. In addition, idence was produced that recombinants resulted from uble infection of cells with these viruses under conions where simple mutation of MEL was most unlikely. Burnet et al. next turned their attention to the luenza strains MEL and WSE, which they could disıguish from one another by six different characters. ıe two viruses were grown together in eggs under nditions where recombination might be expected to cur, and the progeny were examined for the six differtial properties. Out of a litter of 41 viruses, 22 were actly like the parent MEL and 4 like the parent WSE. ıe remaining 15 showed a remarkable reciprocal terchange of properties. Only two of the six properties anged over and they were transferred together, so at only two types of recombinant were found. This sult excludes a random reassortment of characters as explanation of the recombination: it suggests rather at in a casual encounter in the same cell the two ruses may have exchanged some superficial characterics only. It is clear from this work that the cell wall no longer an impenetrable curtain which can protect e virus from the biologist's inquisitive gaze.

MEDICINE IN UGANDA

A WEEK or two ago we commented on the dryness the report of the Sudan Medical Services.[1] Further the Nile ink seems to flow more freely; the report r 1951 of the Medical Department of Uganda[2] is much more lively account. This report not only gives good summary of the work accomplished, but sets out language easily intelligible to the layman the problems efore doctors in the protectorate and their relation to cial and economic conditions.

Although demands for more curative services continue nabated, some African communities are beginning to ppreciate the importance of prevention and are asking r additional health workers. Local authorities are howing an increasing interest in the control of endemic iseases, especially leprosy, yaws, and bilharziasis. t present in Uganda about 3s. per head is spent on he health services each year, whereas the corresponding igure in Great Britain is £8. More money is needed o pay for new services, but these services will also eed men and women suitably trained to run them; many African candidates for training as nurses, midwives, and medical assistants lack a proper vocational outlook. The majority of the diseases which give rise o the heavy demands for increased curative resources are due to defective nutrition, defective housing and sanitation, inadequate water-supplies, and dangerous personal habits. The treatment of many complaints can only be palliative with heavy recurrent costs and with little effect on the patients' disabilities or on the loss of man-power. Some African local authorities tend to equate medicine only with penicillin and similar powerful drugs; yet it should be possible without very heavy expenditure to reduce the prevalence of some of the more disabling diseases: how healthy Uganda can be is shown by the fact that in 1951 not one of the 21 deaths in the European population of about 5600 was attributable to a tropical disease.

Discussing venereal diseases, the report says that "most of the treatment given for syphilis is largely a waste of drugs," since few patients (in one district less than 1%) who start treatment completed the minimum course of injections. Further "schemes of venereal disease treatment having the avowed object of making it easy for the sufferer to get rapid relief, with no concomitant attempts to discourage promiscuity or encourage family life, are of little value to the community." Kwashiorkor is, of course, widespread in Uganda, and much of our knowledge of this disease comes from the Mulago Hospital. A real attempt is being made to tackle problems of maternal ignorances which contribute much to its ætiology. Health education is "centred around the women, aiming at the encouragement of domestic hygiene, clean food, good dietary balance and the mother's pride in and love for her child. Most of this teaching has to be given at rural welfare centres, as health visiting is made difficult by the extent to which the population is scattered. A qualified health visitor is at work in a rural area in Buganda."

The medical staff are to be congratulated on a most readable report which can be commended to any young person who is embarking on a career either in government service or in business in Uganda. A map and a few photographs would help readers unfamiliar with the country.

REACTIONS AFTER EXCRETION UROGRAPHY

SIDE-REACTIONS to the injection media used for excretion urography are well known in all X-ray departments; they are usually mild and transient. Inman[1] has lately tried to classify these reactions in relation to the media normally used. Two drugs are in common use: diodone *B.P.* ('Pyelosil,' 'Perabrodil,' 'Uriodone,' 'Pylumbrin') and iodoxyl *B.P.* ('Pyelectan,' 'Uropac,' 'Uroselectan B,' 'Urumbrin'). Diodone is supplied as a 35% or 50% *w/v* solution and has a pH of 7 to 8; and iodoxyl is a 75% *w/v* solution with a pH of 8·5. For adults the dose of each is 20 ml. Diodone has the outstanding advantage that it can be administered subcutaneously or intramuscularly, if a suitable vein is not available. The solution is usually diluted with sterile water to 15% and administered with hyaluronidase to speed absorption. The iodoxyl compounds, on the other hand, cause tissue necrosis and cannot be given in this way.

From his observations of over 600 patients investigated by intravenous pyelography, Inman finds that the side-reactions fall into two main groups: *general reactions* (vomiting, flushing, and unusual sensations of heat and taste) and *local reactions* (pain at the site of injection or up the arm owing to venospasm, tissue necrosis, and local venous thrombosis). Local reactions were much commoner with iodoxyl. Venospasm occurred in 39% of the 189 patients who were given iodoxyl, but in only 1% of the 286 who had diodone. Inman points out the importance of venospasm and its possible relation to subsequent venous thrombosis: Kemp[2] reported a significant number of cases of venous thrombosis in patients seen 10–14 days after intravenous pyelography. But venous thrombosis is not necessarily confined to patients who show venospasm.

General reactions were equally prevalent with diodone and iodoxyl, suggesting that they have a common cause not directly related to the pharmacological properties of these two drugs. In a group of 12 patients given diodone, Inman demonstrated that the skin-temperature of the forehead rose by 0·8°–2·2°C, and returned to normal after 30–45 minutes. Evidence of mild idiosyncrasy to diodone was found in 1% of the patients: there was puffiness of the eyes and an urticarial or papular skin rash, which were easily controlled by adrenaline. Simultaneous administration of atropine or diphenhydramine ('Benadryl') helped to reduce the number of general reactions—probably, Inman believes, by diminishing vagal stimulation.

Inman suggests that for routine use diodone is the better drug, except in patients with a history of allergy, when iodoxyl is advisable. His conclusions are supported by Mullen and Hughes,[3] who point out that a reaction downstairs—i e, *further south—but it isn't* So I have to remember that whereas Capetown is south of Durban on the map, the ward named Capetown is above—i e, further north—than the ward named Durban

The new *labels may* be *easy* for the young men, or for those with a more elastic geographical outlook, but we older ones find them confusing Ward labellers might take heed of the way streets in New York are named—e g, West 42nd Street There the name gives some clue as to where the street is, but with us the ward's name gives no clue to its location

All the same there may be advantages in calling a room by a *name* I remember a *retired* physician who labelled his room and workshop "Liverpool" so that his housekeeper could truthfully say, when he did not want to be *disturbed*, "I'm sorry, but he has gone up to Liverpool"

* * *

The silence of the night was broken by the creaking of boards in the hotel corridor Someone was stealthily making for my room, and I did what anyone would do in like circumstances—hid my head under the bed-clothes A gentle tap on the door reassured me Pulling myself *together*, I *called out* "*What is it?*" A *female voice* replied "It's a heifer"

After a suitable pause to allow this strange communication to register, the voice continued "Joe would like you to look at her" Joe, the farm bailiff, is an old friend of mine, and I agreed to go After all, I thought, there's no harm in having a look

Joe Sorry to get yer airt, Doc, but there's summat up with yon

Self It's all right, Joe Where is she?

Joe Dairn t'lane

We went down the lane in pitch darkness, without a torch I was on holiday, of course, without the tools *of my trade*, *all I had was head, hands, and general* principles Inspection, palpation, percussion, auscultation—I could manage so much, at least As it happened, the last came first, for I soon heard a sound like the dialling tone, a curious blend of menace and misery, which enabled me to locate the patient Since it was too dark to see anything, I cautiously palpated an unidentifiable part of the beast between its head and its tail Whatever it was, it felt doughy, and light pressure produced a sound like the crackling of thorns under a pot How I wished someone had written an article on "Doughiness and crackling in heifers"! Instinct told me that the signs boded no good, and I ventured my opinion

Self You're right, Joe, there's summat up

Joe Ay, doc, ah were sure there were, and if yer ask me she's 'ad it, and she won't last till morning

Self That's it, Joe, she's had it I suppose heifers are much more lively than this when they're well?

Joe Oh ay, quite different than this

Self That's what I thought This one's very ill, and I *don't think she'll last long* *Can we do anything for her?*

Joe *Oh no, not at this time o'night* Thanks ever so much for coming There's nowt like a second opinion

No, I thought, there isn't, and if my diagnosis was rather indefinite, it was no worse than many another, and my prognosis at any rate was right

* * *

The last patient of a busy surgery on a cold, wet, evening was a rather dirty, rhinorrhœic boy of 8, who had clearly been too timid to take his proper turn in the queue Without a word he handed me a scrap of paper, which read

"Doctor—Do you give Horlicks on the National Health? I was run down recently and bought a bottle but I have now finished it, and it did me good *If it is allowed will you please* give a prescription

Yours truly,

Mrs ———

P S—This boy needs his finger lancing"

The dramatic simplicity of the last line contained an accurate diagnosis, so I was able to ensure that at least one member of that family slept more soundly that night

Letters to the Editor

"UNFIT FOR MILITARY SERVICE"

SIR,—I am concerned *at the apparent* increase certificates lightly given by medical practitioners, general and specialist, stating that a patient is to do his National Service It is not the numerical increase that worries me so much as the unthinking *often unfortunate way in which these certificates* given, so that considerable harm is done on all *I am able to see both sides of this* because I hold civilian appointment and, quite separately, an advisory one to one of the Services

The harm is first done to the patient, who forms view that either he or Service life is unhealthy, usually quite absurd, and in fact Service life is often saving of a nervous and coddled young man

Secondly harm is done to the parents, who probably have visited the doctor and often paid a fee with purpose of acquiring such a certificate, and who develop a paranoid outlook to life in general and Service in particular when their son is asked to after all

Thirdly, harm is *done* to the Service, because situation often leads to a Ministerial inquiry and question in the House of Commons, and the whole may become political, with the added suggestion Service doctors are poor clinicians In fact clinical ability in Service doctors has probably never higher in peace-time than it is *now*

It is of course most valuable to have a balanced experienced opinion on a National Serviceman from own doctor or a competent specialist I have noticed that those doctors who have known something of Service life themselves never give the *type* of certificate about which I am concerned

My particular interest brings me into contact certificates about "blackouts" and headaches Nothing is more helpful than a good description by an unbiased observer of an attack of unconsciousness, and nothing more harmful than the last certificate I read which stated "I have examined X Y Z who is suffering from neurocirculatory asthenia and is quite unfit for form of military service" The signature was grand in its self-description, and in fact the boy was suffering from mild attacks of migraine which had not interfered with his earning capacity (£14 a week)

My plea is for more care and thought in the giving these certificates, particularly in cases of vasomo syncope, which is often due to muscular flabbiness for which the physical training of Service life is one the best forms of treatment

London, W 1

A BARHAM CARTER

CHILD-WELFARE CLINICS

SIR,—Most general practitioners will agree with conclusions in the article by Dr George and his collaborators (Jan 10), but the suggestion that few of them at present equipped *to do* child-welfare work is what surprising Since they deal every day with very conditions which are seen once a week at the and have the added advantage of knowing the family and how it lives, they can hardly fail to have experience

Some already hold afternoon sessions for infants children because so many mothers prefer their doctor's opinion to the clinic medical *officer's* advice in many cases is the same, but it is trusted when given by the well known general practitioner than by the seldom-seen clinic doctor

An increased capitation fee, or indeed any incentive, would encourage *more to do the same* Whether they work in their own surgeries or in the local authority premises is immaterial, and would depend on the opposite direction; and until more evidence is railable it does not seem necessary to urge compulsory E.G. examination of all professional boxers in this untry.

AMYLOIDOSIS

In classical amyloidosis of parenchymatous organs, nyloid is deposited in the skin to a degree which is rely more than microscopical. In the form known as typical or primary systematised amyloidosis, however, ere is striking clinical involvement of the skin or ucous membranes in about half the cases. Naturally ese patients are seen by dermatologists and attract ttention in dermatological circles; but the importance f the syndrome to general physicians has been lately own by Goltz.[1]

Primary systematised amyloidosis differs from classical lardaceous" disease in several respects. It is not sually associated with chronic suppurative disease. The myloid deposits are mainly in and around blood-vessels n connective tissue and muscle, sparing the parenchyma f liver, spleen, and kidneys. Microscopically the amyloid akes up the usual stains, such as methyl violet or congo ed, only with difficulty, and special techniques may be equired to demonstrate it. The skin of the face, neck, xillæ, hands, and perineum shows a variety of changes. t may be studded with papules, which are so discrete nd translucent that they resemble blisters. The infiltration may be diffuse, giving the skin a sclerodermatous or myxœdematous appearance. The resemblance to hypothyroidism may be enhanced by pallor and loss of hair. Hæmorrhages occur into papules or into skin which is clinically normal. Macroglossia is often striking and, together with xerostomia resulting from involvement of the salivary glands, may seriously interfere with chewing and swallowing. The surface of the tongue may be smooth or crowded with pseudovesicles. Involvement of the larynx may cause hoarseness.

The patient's initial complaint may be of breathlessness due to amyloidosis of the heart muscle or valves. Indeed, death in this condition is often the result of cardiac failure. Voluntary muscle may be infiltrated, causing weakness and severe pain, and where the gut is involved there may be constipation, diarrhœa, or even fatal hæmorrhage. Some cases show Bence-Jones proteinuria and non-invasive plasmocytosis of the bone-marrow. This finding is of particular interest, for true multiple myelomatosis may be associated with amyloidosis which may assume the "primary" type of distribution. Wells [2] described a case of primary systematised amyloidosis showing benign plasmocytosis of the marrow. There was no Bence-Jones protein in the urine, but an abnormal beta globulin was detected in the serum. He regarded the marrow changes as reactive—i.e., the result of the disease-producing mechanism—rather than causative. Nevertheless, he treated his patient with urethane, but without benefit.

Some people regard amyloidosis in general as a disease of disordered immunity. Classical amyloid disease develops in association with chronic infection, such as tuberculosis or syphilis; and it also occurs in animals used for the production of antisera. The young doctor who died of primary systematised amyloidosis [3] was sure that he was hypersensitive to milk, and he said he was better when he stopped taking milk and milk products. Another patient was strongly sensitive to egg.[4] Some people believe that the plasma cell is the site of antibody production, and plasmocytosis of the marrow has been shown to coincide with maximum antibody production in hyperimmunised rabbits. This plasmocytosis associated with the appearance of abnormal serum globulins was reported in two cases of sulphonamide sensitivity.[5] The subject is further complicated by the occurrence of localised forms of amyloidosis—for instance, in the heart or skin. Freudenthal [6] described amyloid in a variety of distinctive skin lesions, including epithelioma and nævi. He also gave the name lichen amyloidosus to a condition resembling at times lichen planus; this condition lacks the distinctive pathological lesions of lichen planus, but heavy amyloid infiltration is one of its features. It produces intractable irritation, which is not a symptom of primary systematised amyloidosis.

It may be that we are caught in the terminological trap referred to by Trotter [7] in a discussion of skin myxœdema. The latter term is used in the sense of a generalised disease—i.e., hypothyroidism—or to mean a tissue change detected microscopically. In "amyloidosis" we are comparing a variety of conditions, some generalised and fatal, others purely local, in which the only common factor is a similar tinctorial quality. It seems certain that there are several "amyloids," differing in physical state and probably in chemical composition. Further chemical and cytochemical work is required to enable us to identify comparable states of amyloidosis.

AGE AND SKIN STRUCTURE

The skin of elderly people is characteristically wrinkled and thin, especially in exposed sites, and shows an obvious loss of elasticity. Histological stains nevertheless reveal an apparent increase in the elastic-staining tissue from these sites, although both conventional histology and electron microscopy [8, 9] agree that the chief component of normal human dermis is collagen. Much work with the electron microscope has centred on connective tissue, with the structure and genesis of collagen as its focus.[10] Tunbridge and his colleagues,[11] at Leeds, have now used electron microscopy to investigate the more general fibrous structure of normal human skin, and particularly the changes in elasticity accompanying ageing and certain inherited skin abnormalities. They found only small numbers of elastic fibres in normal skin, and they attribute its "elasticity" to the flexibility of the network structure of the collagen fibres. As others have reported, these fibres are long, banded, straight or smoothly curved fibrils of uniform width, and they are associated with a small amount of fluffy amorphous material which can be removed by trypsin treatment. This is probably the interfibrillar cementing material or ground substance.

Senile skin from exposed sites gives a different picture. There is a considerable increase in amorphous material but not in elastic fibres. The collagen fibres themselves are often short, kinked, and frayed. Treatment with trypsin removes not only the amorphous material, but also the misshapen collagen fibrils and the material responsible for the increased elastic staining, so that only normal collagen fibrils remain. It was also found that normal skin takes up more elastic stain after treatment with pepsin, which attacks collagen. From these results, it is reasonably concluded that in senile skin there is no increase in elastic tissue, but rather a degeneration of some of the collagen fibrils, whereby they acquire a capacity for taking up elastic stain and a susceptibility to the action of trypsin. The puzzling feature is that these changes seem to develop only in skin taken from exposed areas of the body. A similar change was found in pseudoxanthoma elasticum—a rare disease whose manifestations include a general looseness of the skin, a tendency for striæ to form, and

PRACTICAL PENICILLIN

SIR,—In 1947 when in general practice, I treated patients suffering from boils and carbuncles with systemic penicillin[1] At that time I used the oil-wax suspension (1,250,000 units in 10 ml) I gave a single dose of 10 ml I treated patients with otitis media, both in the acute and chronic phases, with the same oil-wax suspension, but I gave them the 1,250,000 units in four daily doses of about 300,000 units each[2]

My treatment differed from that described by Mr Cohen (Jan 24) in that, apart from the application of a piece of gauze or lint on any discharging area, there was no local treatment

For over a year now I have been in the habit, if the patient did not respond to penicillin injections within thirty-six hours, of giving aureomycin, which I found to be far the most effective antibiotic in staphylococcal infections Aureomycin has the added attraction that it can be taken by mouth

During the last twelve months I have not resorted to incision at all In 2 cases, however, when the induration had subsided I was able to aspirate the pus

Enfield I GOTTLIEB

THE MEDICAL SERVICES IN THE KOREAN WAR

SIR,—Dr Binning (Jan 24) has expressed anxiety that whole blood was not available for Commonwealth medical units It would indeed be strange if such were the case, but let me assure him that whole blood is supplied by the United States Medical Services to all United Nations medical units

The point which I am sure the writer of your article wished to make was that American policy was to give whole blood rather than plasma to types of cases in which we prefer to give plasma

ŒSOPHAGEAL CONTRACTION AND CARDIAC PAIN

SIR —In your issue of Dec 6 Dr William Evans presents an impressive series of fluoroscopic observations on the motility of the œsophagus and its possible relation to "cardiac-like" pain Although in a certain number of the patients described the pain may be related to œsophageal dysfunction, the pathological significance of some of the observed phenomena must be questioned

The "œsophageal arrhythmia" discussed by Dr Evans sounds very much like "tertiary contractions" which Templeton and others have described in many people, especially in the older age-groups, with a normal œsophagus In their extreme form these contractions have been called "curling" and appear not to have any pathological significance, though they are sometimes associated with œsophageal diverticula or carcinoma

Dr Evans further attributes the observed retrograde propulsion of barium to probably antiperistaltic waves So far as I know, no one directly recording œsophageal motility has ever found true antiperistalsis, and the return of barium towards the upper œsophagus may be explained on the basis of rebound of the bolus, which is propelled forward by peristalsis and encounters a physiological block in its path (call it cardiac sphincter, œsophago gastric junction, or what you will) Two of my colleagues (Ingelfinger and Kramer) and I have studied œsophageal motility with simultaneous fluoroscopic observations and direct pressure recordings with balloons or an electrical recording device Although we have seen a good many cases where barium flowed cephalad, we have never observed retrograde progression of pressure waves

The temporary halt of the barium meal at the diaphragm or just above it is a normal event of varying duration in different subjects

Finally, the partial or total pinching off of the œsophagus 1–2 cm above the diaphragm again is a normal phenomenon seen in every subject on deep inspiration From a few fluoroscopic observations in subjects where a small tenuous dome is seen to project above the diaphragm and attach at the site of the pinchcock, we have favoured the theory that this pinching off is due to the action of the phrenico œsophageal membrane at the site of its attachment to the œsophagus

ACTION OF PARATHYROID HORMONE

SIR,—Your leading articles of Jan 10 on hyperparathyroidism and nephrocalcinosis (idiopathic renal acidosis) certainly emphasise the complexity of the problem when both kidney and parathyroid are involved in one syndrome I should like to draw attention therefore to an observation which I made last year in the veterinary field, and which may be pertinent

Renal osteodystrophy (rubber jaw), a not uncommon condition in the dog,[1] is assumed on good evidence[2] to be *primarily a renal disease The lesions of osteitis fibrosa* which subsequently develop are associated with hypertrophy of the parathyroids,[1–3] and apparently the degree of hypertrophy and overactivity of the gland is directly related to the stage of the renal lesion[2] The cause of this lesion is so far unknown, but in dogs there is a high incidence of *Leptospira canicola* infection, which is known to produce nephritic lesions resembling those in osteodystrophy[4] Apparently in man there is no single similar condition that occurs so regularly or follows so unvarying a course Incidentally the canine condition was first described by Dr Tom Hare before the Royal Society of Medicine[5]

Last year I attended a trio of cases which constitute an unusual coincidence or alternatively provide food for thought regarding associated renal parathyroid syndromes in the dog The cases will be described elsewhere, but briefly the *facts are as follows*

In one set of kennels three closely related dogs (sire 5 years, son 3 years, stepdaughter 3½ years) were destroyed within a period of 6 weeks All had uræmia arising from chronic nephritis Of the two younger dogs one showed advanced coincident osteitis fibrosa (renal osteodystrophy), the other bilateral renal calculi The sire was found to have pronounced hypertrophy of one adrenal gland No lesions were *found in any* of the dogs except those in the kidneys There is good evidence that the calculi had been present in the bitch at under 1 year of age

Renal calculi are rare in the dog, although cystic calculi are common[6] Primary parathyroid tumour has never been satisfactorily demonstrated in the dog to my knowledge It is tempting to suggest that in this case also (as in that showing osteitis fibrosa) a primary renal lesion preceded the mineral imbalance, leading in one instance to calculus formation and in the other to bone dystrophy As to the hypertrophy of the adrenal in the third case, I make no comment, but I have previously suggested[1] that examination of this gland in cases of chronic nephritis in the dog especially when associated with osteitis fibrosa, might demonstrate hypertrophy if

REVENTION OF RHEUMATIC FEVER

AMERICAN HEART ASSOCIATION'S STATEMENT *

HEUMATIC fever is a recurrent disease which can be rented. It is now generally agreed that both the al and recurrent attacks of the disease are usually ipitated by infections with beta hæmolytic strepto- i. Therefore, the prevention of rheumatic fever and matic heart-disease depends upon the control of ptococcal illnesses. This may be successfully accom- hed by (1) early and adequate treatment of strepto- al infections in all individuals and (2) prevention of ptococcal infections in rheumatic subjects.

gnosis and Treatment of Streptococcal Infections

n the general population at least 3% of untreated ptococcal infections are followed by rheumatic fever. ong certain individuals, especially those with previous umatic fever, the incidence is much higher. Adequate early penicillin treatment, however, will prevent st attacks of rheumatic fever and eliminate strepto- ci from the throat.

DIAGNOSIS OF STREPTOCOCCAL INFECTIONS

n most instances it is possible to recognise strepto- cal infections by their clinical manifestations but oratory tests may assist in establishing the diagnosis.

idemiology

he seasonal pattern and presence of similar cases in the nmunity or household may be helpful. For example, ptococcal infections in the northern United States are st common from January through June. Likewise, a case scarlet fever in one child would suggest that a sore throat another has the same ætiology.

mptoms

a) Sore throat—onset sudden, in the tonsillar area, not the trachea.

b) Headache—common.

c) Fever—variable, but generally from 101° to 104°F.

(d) Abdominal pain—common, especially in children. Not common in adults, but does occur.

(e) Nausea and vomiting—common, especially in children.

(f) These symptoms are usually *not* present: (1) simple ryza, (2) cough, (3) hoarseness.

gns

(a) Red throat—frequently beefy red, but if seen early the dness may be mild.

(b) Exudate—usually present.

(c) Glands—swollen, tender tonsillar glands at angle of jaw.

(d) Rash—scarlatiniform (characteristic of scarlet fever; t common).

(e) Discharge—otitis media and sinusitis indicated by erous or purulent) aural or nasal discharge are frequent mplications of streptococcus pharyngitis.

aboratory

(a) White blood-count—generally over 12,000 and in ildren frequently over 20,000.

(b) Throat culture—positive for hæmolytic streptococci.

herapeutic Response

Almost without exception patients with streptococcal fections are vastly improved within 24 hours after penicillin as been started and the temperature normal, or nearly so. his therapeutic response is characteristic and if it does not occur, the chances are much against the disease being due to hæmolytic streptococci.

TREATMENT OF STREPTOCOCCAL INFECTIONS

In order to be effective, treatment should be started immediately when a streptococcal infection is suspected and continued for sufficient time to eradicate the streptococci from the throat.

Penicillin is the drug of choice for treating streptococcal infections. Both the oral and the intramuscular routes of administration have been utilised successfully for penicillin therapy of streptococcal infections. Intramuscular injections have been proved to prevent rheumatic fever. The data on the value of oral penicillin as a preventive is less complete.

Oral administration in contrast to intramuscular administration has these advantages: (1) it is not as distasteful to many patients; (2) it requires fewer physician visits. It has these disadvantages: (1) larger amounts of penicillin must be used; (2) it is difficult to administer to vomiting or refractory children; (3) in some adults it gives rise to persistent diarrhœa and pruritus ani; (4) it is difficult to be sure that treatment is continued for sufficient time and given in proper relation to meals to be effective.

Recommended Schedules

Intramuscular penicillin.—(1) Children—one intramuscular injection of 300,000 units of procaine penicillin with aluminium monostearate in oil every third day for three doses.

(2) Adults—one intramuscular injection of 600,000 units of procaine penicillin in aluminium monostearate every third day for three doses. (Note: Less preferable, but usually effective—two doses as above at three-day intervals.)

Oral penicillin.—(1) First five days: 200,000 to 300,000 units one half to one hour before meals and at bedtime (total of 800,000 to 1·2 million units per day in four divided doses; smaller amount children, larger amount adults).

(2) Second five days: 200,000 to 250,000 units one half to one hour before meals (total 600,000 to 750,000 units per day in three divided doses). (Note: To be effective, therapy should be continued for the entire ten days even though the temperature may return to normal and the patient may feel better within one or two days.)

Combination of intramuscular and oral penicillin.—Therapy may be begun with one injection of penicillin (300,000 units of procaine penicillin with aluminium monostearate in oil) and then, beginning three days after the injection, continued for an additional seven days with oral penicillin according to the schedule (2) outlined above.

Other medication.—(1) Aureomycin is less effective than penicillin in controlling streptococcal infection but is especially useful in those sensitive to penicillin. Dosage: Total 10 mg. per pound of body-weight in four divided doses daily for two days. Cut dose in half for remaining eight days of therapy.

(2) New preparations of penicillin. These may be effective and even preferable to the treatment schedules outlined, but at present they have not had sufficient trial to warrant their recommendation.

(3) Other antibiotics. At present there is inadequate data on their value.

Not recommended for treatment.—(1) Penicillin troches or lozenges, (2) penicillin followed by sulphonamides, (3) sulphonamide drugs. (Note: Recurrences of streptococcal infection should be treated as primary attacks.)

Prevention of Streptococcal Infections

GENERAL RULES FOR PROPHYLAXIS

Who Should be Treated?

All individuals under the age of eighteen who have had rheumatic fever or chorea and all those over this age who have had an attack within five years.

When Should Prophylactic Treatment be Initiated?

At the end of the second week of the attack of rheumatic fever or at any time thereafter when the patient is first a firm inelastic layer of fascia This fascia is particularly strong and closely applied to the muscles in the lower third of the leg A leak outwards from this musculo-fascial structure would be effective in transmitting the raised pressure inside the fascial sheath outwards, irrespective of whether the rest of the valves within the pump were normal or abnormal

---

* Prepared by the association's council on rheumatic fever and congenital heart-disease. The statement is signed by: BURTIS B. BREESE, M.D., chairman, committee on prevention of rheumatic fever; MARJORIE T. BELLOWS; EDWARD E. FISCHEL, M.D.; ANN KUTTNER, M.D.; BENEDICT F. MASSELL, M.D.; CHARLES H. RAMMELKAMP, jun., M.D.; EDWARD R. SCHLESINGER, M.D. Copies are obtainable from the medical director of the association, 44, East 23rd Street, New York 10, N.Y.

In conclusion I should like to stress two points First, the presence of an ulcer in a leg presents a diagnostic problem in sorting out the factors responsible for it, some of the factors are arterial ischæmia, infection, trauma, general disease, or venous incompetence which may lie in the superficial veins, deep veins, or communicating veins, or a combination of these three The younger group of patients are usually extremely keen to have any operative treatment which holds out hope of cure The older patients do extremely well on supportive treatment, as is well known

Ulcer of the leg is such a common, everyday disease, and is socially so unpleasant and economically so important, that the subject deserves a good deal of interest and research

BOVINE TUBERCULOSIS AND HUMAN TUBERCULOSIS

SIR,—Mr Pitcher, in his letters of Dec, 6 and Jan 24, makes the mistake of estimating the incidence of pulmonary tuberculosis from notification statistics He overlooks the fact that improved case-finding could account for the increased morbidity-rates he quotes Indeed, one is tempted to suggest that the counties whose health authorities were astute enough to advise attestation of dairy herds are the counties where improved case-finding methods are likely to have been encouraged and developed

The uncertain remote benefits of drinking tuberculous milk must be compared with the certain immediate risks of primary infection Only the survivors of such infection will enjoy any increased resistance to tuberculosis Therefore, before publicly advocating oral vaccination with virulent bovine bacilli, Mr Pitcher should examine and quote the mortality-rates from non-respiratory tuberculosis (especially in young children) in the counties he has studied

TUBERCULIN SENSITIVITY

SIR,—The interesting paper by Dr Edwards and Dr Palmer (Jan 10) illustrates the value of qualitative examinations of the tuberculin reaction, but they do not seem justified in suggesting that the low-grade sensitivity to tuberculin shown by children in Egypt and India may be due to non-tuberculous infection It is well known that sensitivity to tuberculin can vary greatly Bluhm [1] found that it diminished with healing of tuberculous lesions Reversion to complete insensitivity in those who had previously reacted is a recognised phenomenon and has occurred, according to Rich,[2] in between 2% and 21% of the persons studied Indeed, although this is rare, it is possible to suffer from moderately active tuberculosis without having a positive tuberculin reaction [3 4] At the other end of the scale there are those who, although not suffering from tuberculosis react to tuberculin in fantastically high dilutions Lyle Cummins [5] found Africans who were positive to 1/10,000,000 tuberculin, and his work has been confirmed by others Europeans rarely react so strongly, and of 50 tuberculous patients in my hospital not one was positive to 0· of 1/1,000,000 tuberculin when tested recently

If the capacity of Africans to react to tuberculin w taken as a standard, the reaction of Europeans w be uniformly "low-grade", but this would not b reason for suggesting that the European reaction w non specific in origin It seems more logical, the to conclude that for reasons that are not yet ob tuberculin sensitivity may vary widely between diff groups of people, than to conclude that an orga other than the tubercle bacillus is responsible whe tuberculin reaction is minimal

Surely, however, the crucial question is the cl significance of variation in the tuberculin reaction is generally agreed that acutely sensitive Africans more liable to tuberculous disease than those who not react strongly to tuberculin, and that loss of se tivity does not by any means indicate loss of resista to infection It will be most important therefore in the future Dr Edwards and Dr Palmer can indic the mortality and morbidity rates from tuberculosis the various groups of children who have been the subj of their present research It seems unlikely that th implication can have escaped the notice of such care workers Certainly the protective value of B C G vacc tion, from a statistical point of view, would be grea enhanced if many of those who were vaccinated w already highly resistant to tuberculosis

Dungannon co Tyrone

E F JAME

STREPTOMYCIN-P A S HYPERSENSITIVIT

SIR,—May I make some comments on Dr Mars paper on this subject [1]

It seems that his patient showed hypersensitivity t p aminosalicylic acid (P A S), streptomycin, chloramphe penicillin, and a local anæsthetic solution, and that he sugg the aggregation of P.A S , streptomycin, chloramphenicol, a the unspecified local anæsthetic into one group of rea agents—"substances containing a benzene ring with attached amino or nitro group" He then suggests th penicillin is in a second group, with a common factor w streptomycin, for both these substances are said to b "complex proteins derived from moulds" Furthermore, remarks on the alleged importance of m aminophenol P A S hypersensitivity

When one patient shows hypersensitivity to several dru it is hard to decide whether one is dealing with a mixture specific reactions or whether there is a true "cross reacti By the term "cross reaction" I mean the development in th organism of a capacity to react abnormally to one or m different chemical structures, each quite different in stru from the original reactive agent By the term specific react I mean a reaction invariably dependent on a part chemical structure, and the specific structure does n necessarily include the entire molecule

From my own and from published observations it see that in patients who show skin hypersensitivity to P.A.S definite hypersensitivity reactions have been demonstra when pure salicylates, phenols, carboxylic acids of benze and carboxylic acid phenols are applied to the skin. A those tested have been hypersensitive to various prim aromatic amines (using the term "aromatic amine" for th compounds composed of an amino group directly attached to benzene ring but not including those with an amino g only in a side chain) I have not yet seen a reaction in su patients after the application of either secondary or ter mixed aliphatic aromatic amines Moreover, I do not kn of any reactions to benzene derivatives containing amino amido groups in side chains only, unless the structure the compound suggested the likelihood of its in vi transformation to a primary aromatic amine

Though a primary aromatic amine structure seems esse to the skin reaction caused by P A S , it is also clear that qu simple additions to the structure will alter such reactions For instance, a patient whose skin was hypersensitive to P.A.S reacted severely to the application of aniline, but more mil to 1, 4 benzenediamine, and not at all to p aminobenz

OUTINE X-RAY EXAMINATION OF THE CHEST AT AN ANTENATAL CLINIC

Audrey Freeth
M.B. Lond., M.R.C.O.G.
ST ASSISTANT OBSTETRICIAN, EASTERN DISTRICT HOSPITAL, GLASGOW

Radiology is acknowledged as the best of the routine eans of examining the chests of apparently healthy ople, and its use in this way is particularly valuable in e care of pregnant women. We decided to look for nsuspected tuberculosis by making X-ray examinations the chests of mothers attending an antenatal clinic a district where tuberculosis was common; and this per describes the results.

EARLIER SURVEYS

It is hard to compare the figures that have been tained by previous surveys of this kind, because of the ifferent standards used in deciding which patients to nclude. For example, Eiscle et al. (1942) excluded all omen known to have tuberculosis—a group of 62 with inimal fibrotic lesions, and a further group with rimary calcified complexes. However, the figures of cker and Bryant (1943) are comparable with the results f Eisele et al. Roe (1946) does not include primary alcified lesions, and Jacobs (1946) excludes 39 women ith calcified shadows only. Graham (1941) mentioned hat 206 women in his series were "contact" cases with alcium deposits in the hilum and lung parenchyma. Both Perlberg (1940) and Dawson (1945) included calcified pulmonary lesions. Bickerstaff et al. (1951) said that ver half the cases they discovered were diagnosed as minimal lesions, and over one-third as moderately or far advanced, and that two-fifths of the cases were probably active; these figures, they concluded, "indicate the significance of what was classified as tuberculosis."

The results of these and other earlier investigations are set out in the table.

TUBERCULOSIS IN GLASGOW

In Glasgow the death-rate from pulmonary tuberculosis in 1949 was 1010 per million population, compared with 590 in Scotland as a whole, and 403 in England and Wales. The medical officer of health for Glasgow (1949) says that the mortality-rates have remained high since the early years of the late war, largely because of more deaths among young women between the ages of 15 and 25 (and even up to 35), and because of more tuberculosis among men over the age of 45. The total number of cases of pulmonary tuberculosis notified in Glasgow in 1949 was 2829; 1374 (43%) were women, of whom 1196 (87%) were of child-bearing age (15–45).

McIntyre and Armstrong (1948) treated 150 Glasgow women who became pregnant while suffering from tuberculosis between January, 1947, and March, 1948. During this time 16 women (10·7%) died and 14 (9·3%) became worse. In 42 cases the disease was first discovered during the pregnancy, and in 38 of these the disease was active: 7 of the women with active disease died (all of them had been discovered late in pregnancy); and a further 3 women, diagnosed in the puerperium, also died.

THE PRESENT INVESTIGATION

The clinic chosen for our investigation is in a working-class area. In this area women known to have tuberculosis are referred to a special unit when they become pregnant, and these cases were excluded from our series. Apart from this, there was no selection of patients in the series. As it happened, only 1 woman with known tuberculosis reported to the clinic during the investigation; all the other cases found were unsuspected.

During their first visit to the clinic 576 patients were asked to attend for X-ray examination of the chest, and 541 (94%) did so. One 15 by 12 in. A.-P. film was taken. Patients showing active or healed tuberculous lesions were asked to attend for a second film three to six months later, and 69% did so. Of the 541 films taken, 477 were normal. The other 64 (13·4%) showed some abnormality.

Evidence of tuberculosis was found in 29 women (5·3%), and another 4 had calcified glands, with no lung changes. Of the 29 tuberculous cases, 12 showed only calcified areas in the lungs, while the remaining 17 (3·1%) showed active, inactive, or fibrotic lesions. In 4 cases the disease was definitely active (0·74% of the total), and a further woman, who was reported to have lesions of doubtful activity, declined further investigation: 8 cases showed inactive lesions, and 4 had healed fibrotic lesions.

The active and inactive cases were re-examined after delivery. The 4 active cases were reported to be unchanged. Of the 8 inactive cases, 2 failed to attend for examination, 2 had become active, in 2 others activity was doubtful, and in the remaining 2 the condition remained unchanged.

The other abnormalities found included mitral stenosis (6 cases), emphysema (2), old pleurisy (3), peri-apical pleural thickening (2), and inflammatory changes (6).

RESULTS OF PREVIOUS SURVEYS BY ANTENATAL X-RAY EXAMINATION OF THE CHEST

Author, place, and time	Method	No. in survey	No. with evidence of tuberculosis	No. with active disease	—
Eisele and Mann (1938), Eisele et al. (1942); Chicago, 1934–41	Screening	10,968	172 (*1·6%*)	74 (*0·6%*)	Excludes known tuberculosis and primary calcified complexes
Tucker and Bryant (1943); Chicago, 1939–42	Screening	1000	29 (*2·9%*)	18 (*1·8%*)	Comparable with figures of Eisele et al.
Graham (1941); California, 1937–39	Radiography	800	30 (*3·7%*)	8 (*1%*)	24 had significant parenchymal disease. Excludes 206 "contact" cases with calcium deposits in hilum and parenchyma
Perlberg (1940); Jersey City N.J., 1938–39	Screening	2834	130 (*4·5%*)	3 (*0·1%*)	18 inactive, 14 suspicious cases, and 95 healed primary lesions
Dawson (1945); Dunedin, N.Z., 1942–44	Radiography	1000	30 (*3·0%*)	6 (*0·6%*)	Includes 25 calcified lesions only in lungs
Roe (1946); Uxbridge Chest Clinic, Middlesex, 1943–45	Radiography	1088	10 (*0·9%*)	2 (*0·18%*)	3 inactive and 5 suspicious cases. Excludes primary calcified lesions
Jacobs (1946); Paddington, London, 1943–46	Screening	4430	107 (*2·4%*)	38 (*0·9%*)	Excludes 39 cases with calcified shadows only
Bickerstaff et al. (1951); Muscogee, Georgia, 1946–49	Miniature radiography	3576	43 (*1·2%*)	14 (*0·4%*)	In the 14 active cases tuberculosis was unsuspected

Five hours after treatment was started cortisone became available, 100 mg was given intramuscularly and 200 mg orally Meanwhile general improvement had continued, and the blood pressure was now 90/60

Cortical extract was now omitted, but deoxycortone was given in 10 mg doses twice daily for another week, and cortisone in gradually decreasing doses for five days Antibiotics were given for a further four weeks, as the illness was marked by a relapse of fever with a joint effusion in the third and fourth weeks

The patient was discharged five weeks after admission He has been followed up for five months, during which he has maintained excellent health and has been free from all sequelæ The blood-pressure on discharge was 115/70, and subsequent readings have been substantially the same

Investigations

Blood culture on admission grew meningococcus type II Lumbar puncture on the day of admission yielded turbid cerebrospinal fluid under a pressure of 230 mm of water, containing large numbers of polymorphs and a few gram negative intracellular diplococci, culture was sterile A blood count showed Hb 84%, white cells 5500 per c.mm (neutrophil polymorphs 79%, eosinophils nil, lymphocytes 9%, monocytes 5%, metamyelocytes 6%, myelocytes 1%) Lumbar puncture and blood culture a week after admission gave normal results in all respects

The blood electrolytes were investigated repeatedly, but were within normal limits except for a slightly low sodium level (315 mg per 100 ml) on the first day

Urinary 17 ketosteroids, estimated on the tenth, twelfth, and thirteenth days, amounted to 2 2, 2 9, and 2 8 mg per day, three and a half months after discharge the value was 5 2 mg per day

In this case the diagnosis of the Waterhouse-Friderichsen syndrome (sometimes a matter of doubt) was probably as well authenticated as can be expected in the absence of confirmation at necropsy Dr Stanley Banks kindly read a précis of the case notes and agreed to this diagnosis In his opinion it was a case of meningococcal septicæmia of the mixed encephalitic and adrenal type [1]

One might ask why these cases on recovery from acute illness do not require long-term replacement therapy as in Addison's disease our patient only had adrenal cortical extract for three hours, cortisone for five days, and deoxycortone for a week Histological study of the adrenal from a fatal case, however, showed that although the cortex was grossly damaged about a third to a quarter of it was affected only by œdema, being probably capable of functional recovery had the patient survived In this respect the low values for urinary 17-ketosteroids in our patient are interesting He was postpubertal, but even three and a half months after his illness excretion was rather low (5 2 mg per twenty-four hours)

Of particular interest was the apparent excellent response to large intravenous doses of adrenal cortical extract given over a short time—120 ml in three hours Cortisone was only available later, when anxiety for the survival of the patient was much less, though it probably contributed to the recovery Possibly, where adrenal cortical extract has previously failed in these cases [2 3] the dose has not been large enough

Whether the beneficial effect of the adrenal cortical extract should be credited to the deoxycortone content of the extract or to other substances is not clear These preparations are, I understand, assayed biologically by their action on the blood electrolytes Eucortone probably contains cortisone, though only in negligible amounts But these adrenal cortical extracts, besides the known crystalline compounds of the perhydrocyclopentenophenanthrene series (such as cortisone, deoxycortone, and progesterone of the 21 carbon pregnene group, androsterone of the 19 carbon etiocholane group, œstrone, and other 18 carbon phenols) contai amorphous residue which is chemically unidentifi From the work of Kendall [4] and others [5] it seems th this residue produces powerful physiological effects, these may be of therapeutic value in states such as Waterhouse-Friderichsen syndrome

I am indebted to Dr E N Allott, Dr H S Banks H V Morlock, Dr G Nelson, and Dr G F Thomas help with this case report

London, N W 6 I A Macyt

TABLET-IDENTIFICATION BOX

Sir,—The experience of producing a tablet identifica box for this hospital has demonstrated the difficul and possible danger in trying to use only a box f this procedure I suggest that anyone who is conte plating such a box should consider the following poi

The box should be produced with the coöperation of pharmacist, if not by him alone He can readily ob *complete set of locally prescribed coloured tablets from* retail pharmacists In my opinion white tablets, wh *coated or plain, scored or otherwise marked,* are b excluded

The total number of coloured potent tablets and caps for this area is about fifty, so that our box is little m than pocket-sized

When the capacity of the box is decided, the tablets a capsules can be arranged according to colour and sh The following precautions will then be necessary

1 A warning should be attached to the box stating it should only be used in conjuction with two m reliable sources of information (*a*) the doctor w prescribed the tablets, who should have a filed rec of them in his surgery, and (*b*) the chemist who d pensed the tablets, whose name and address will found on the container if the parent produces this
2 The colourings of tablets, more especially the o non proprietary ones, are liable to variation wi limits, and brightly coloured tablets of green and can change sufficiently in a perspiring parent's hand make identification by colour alone most difficult

These points ought to be brought to the attenti of every new house physician The box then beco a safe as well as a useful additional source of informati

Kent and Canterbury Hospital,
Canterbury JOHN C SMITH

PERFORATION OF COLON AFTER BARIUM ENEMA

Sir,—With reference to the letter which was publi under the above head from Mr. A V Pollock on Jan. I was not consulted before publication, and I sh welcome an opportunity of correcting one or two wr *impressions which the letter has created*

The patient in question was admitted to the West Lon Hospital under my care As registrar to my surgical u Mr Pollock performed the routine sigmoidoscopy, which later followed by the passage of a barium enema into peritoneal cavity through a rent in the sigmoid colon Pollock assisted me with the first operation at which laceration of the sigmoid was sutured and cæcostomy p formed, but he had left the hospital before the splenic flex was resected The patient is still in hospital and his recov is not yet beyond doubt

It is my intention to publish a full account of t case in due course

London, W 1 G F GRANT BATCHELOR

*** We have shown the above letter to Mr Pollock, w replies "I naturally wrote to Mr Batchelor asking permission to publish this case *Hearing* nothing over a week I left his name out of my communicati believing that he did not wish to be associated with case which reflected no credit on me The facts of t case are exactly as stated in my letter of Jan 10' Ed L

4 Kendall H C *Proc Mayo Clin* 1940, 15, 297
5 Tait J F Simpson, S A, Grundy, H M *Lancet* 1952 i

The chemical branch of the L.C.C. public health partment make daily measurements of the amount of oke and sulphur dioxide in the atmosphere at County ll and elsewhere. Some of the results obtained at time of the fog are shown in the accompanying table. e maximum averages were reached over the weekend ling at 10 A.M. on Monday, Dec. 8. These figures re higher than any that have been traced in the L.C.C. ords, which, for sulphur dioxide, date back to 1932.

In a report to the borough's public-health committee, . E. H. R. Smithard, medical officer of health for wisham, says that 228 deaths were registered in wisham in the fortnight ended Dec. 20, compared h 76 and 95 deaths in the corresponding fortnights 1951 and 1950 respectively. Of those who died in this tnight, 130 were men and 98 women; 104 were over age of 75, and all but 8 were over 45. A striking ture of the Lewisham figures was the abnormally ge number of deaths in the Sydenham registration trict, as compared with the other two districts in the rough. Dr. Smithard suggests three possible explanans:

(1) An older population in the Sydenham area.

(2) A denser fog caused by geographical configuration.

(3) A more poisonous fog due to greater atmospheric llution in that part of the borough.

rther inquiries are being made. Dr. Smithard mentions e new and popular type of slow-burning fire, which commonly stoked up to keep it going all night, as a ely cause of increased atmospheric pollution.

Influenza

In the week ended Jan. 24 there were 132 deaths om influenza in the 160 great towns of England and ales, compared with 72 in the preceding week. This ings the total number of deaths from influenza in the eat towns this year to 255; at this time last year e total was 110. The outbreak is still confined to the uthern half of England, with a large number of cases the London area. Of the 132 deaths in the week ded Jan. 24, 78 were in the London and South Eastern gions; and 112 of those who died were aged 55 or ver. Only localised outbreaks have so far been reported om the north of England and Wales.

Dr. William Bonne, director of the W.H.O. division f communicable diseases, describes the epidemic as ild in all countries. The A-prime virus which has been olated in several countries seems to be closely related o the virus responsible for the outbreaks in the winter f 1950–51.

Emergency Bed Service.—Last week applications for admision to hospital for general acute cases averaged about 350 day; but by Monday of this week the daily total had ropped to 293. On Tuesday the red warning was replaced y a yellow warning, even though the proportion admitted n the previous week was 88%—a level at which no warning sually operates. It was thought that the improved position as largely due to the excellent response by hospitals to last eek's red warning, and that the need for special measures ontinued.

Estimate of Births

The Registrar-General[1] estimates that in the quarter ending March 31 this year live births in England and Wales will number 170,000. The provisional estimate for the quarter ending June 30 is 165,000, giving an estimated total in the first half of this year of 335,000. Last year births in the first two quarters numbered 173,503 and 174,089, making a total of 347,592.

Statistics for England and Wales in 1952

The Registrar-General[2] has reported provisional statistics for England and Wales in the year 1952 and for the fourth quarter of that year. These figures, along with the corresponding figures for 1951, are as follows:

Rate	*Whole year*		*Fourth quarter*	
	1952	*1951*	*1952*	*1951*
Live birth (per 1000 pop.) ..	15·3	15·5	14·3	13·9
Stillbirth (per 1000 total live and still births)	22·6	23·0	23·1	24·2
Death (per 1000 pop.).. ..	11·3	12·5	12·4	11·0
Infant-mortality (per 1000 related live births)	27·6	29·7	29·0	28·5

The stillbirth and infant-mortality rates for the year are the lowest ever recorded in this country.

Medicine and the Law

A Patient's Bequest

THE law recognises that the confidential relationship of doctor and patient (like that of solicitor and client and certain other relationships) establishes an opportunity of influence. In Estate of Smith deceased, Creditor *v.* Markowicz,[1] a doctor put forward as plaintiff a will of 1949 which he had himself made for an old lady, his patient, aged 89. Under this will he was to obtain substantial benefit. The defendant, Mrs. M., was executrix and beneficiary under a will of 1947 which had been drawn for the old lady by her solicitors. There were two questions for the jury. First, at the time when the will of 1949 was executed, did the deceased know and approve its contents? Secondly, was the execution of the will procured by the undue influence of the doctor? As Mr. Justice Barnard put the problem to the jury—was the doctor an honest man who behaved foolishly or a wicked man who took advantage of his position as a doctor to get money out of the old lady? After a prolonged hearing and after deliberating in their room for eighty minutes the jury found in favour of the doctor.

As already stated, the doctor-and-patient relationship is deemed analogous to that of solicitor and client. A solicitor can obtain benefits under a will which he draws up for a client; but if the benefits are substantial he will be expected to show that the testator was capable of making the will and knew and approved its contents and was not subjected to undue influence. Professional prudence will persuade the solicitor to send the client to another solicitor who can give independent advice and who will make a proper note of the instructions received and the advice given. In Radcliffe *v.* Price (1902) a gift by a patient to a doctor was set aside on the ground that the patient had no independent advice, even though there was no suggestion of pressure or of weak intellect. There is, however, a curious legal difference between the case of a gift made during life and a legacy under a will. The former courts of equity thought that the natural influence arising from such relationships as those of doctor and patient, exerted by those who possessed it for the purpose of obtaining benefit for themselves, was undue influence. With wills, as was stated by Lord Penzance in Parfitt *v.* Lawley (1872) in a passage read by Mr. Justice Barnard to the jury, it is otherwise. Such relation may lawfully be exerted to obtain a legacy so long as the testator understands what he is doing and is a free agent. In the recent litigation there was much argument as to the onus of proof. The learned judge quoted the judgment of Sir Gorell Barnes in Spiers *v.* English (1907) to the effect that the onus is not "specially heavy" upon a person who obtains and puts forward a will in his favour. "I doubt whether the fact of his having been instrumental in making a will under which he substantially benefits makes any difference to the presumption of law." Mr. Justice Barnard told the jury that to be satisfied that there had been undue influence they must be satisfied that, when the transaction had been finished, the testatrix would have said "it is not my wish: I had to do it"; there must be coercion.

One intriguing remark fell from the judge's lips. If, he said, the jury were satisfied that the doctor had

[1] *Times*, Jan. 23.

If no other syringe is available in an emergency the technique can be adapted for intravenous injection. Advantage is taken of the recoil by maintaining gentle pressure on the rubber piston while the vein is being sought. The release of this pressure (insufficient to inject solution) will draw blood from a vein.

From my own experience, the glass container is best dipped into hot or boiling water for a moment before use. This serves two purposes: the solution is warmed and the injection is infinitely less painful; the rubber piston is thereby caused to run smoothly down the glass cylinder, instead of stiffly or in jerks.

Stockport D N BARBER

UNUSUAL PNEUMONIA

SIR,—In common with other physicians I have recently seen many cases of pneumonia, and I think it is worth recording some unusual features in these cases.

They have all resembled the usual descriptions of virus pneumonia in so far as they have had (1) mucoid sputum and (2) no leucocytosis. They have, however, differed considerably from the usual accounts of virus pneumonia in so far as (1) pleural pain has been prominent, (2) physical signs have been gross, and (3) sterile pleural effusions—usually comparatively small and encysted—have often complicated the illness.

London, W 1 M H PAPPWORTH

Parliament

Therapeutic Substances Bill

IN the House of Lords on Jan 27 the Therapeutic Substances (Prevention of Misuse) Bill was read a first time. The Bill makes further provision as to the substances other than penicillin to which the Penicillin Act, 1947, may be applied by regulations, and provides for the relaxation in certain cases of the restrictions imposed by that Act. The Bill is discussed in an annotation on p 280.

QUESTION TIME

Adoption of Children Inquiry

Replying to a question, Sir DAVID MAXWELL FYFE, the Home Secretary, said that he and the Secretary of State for Scotland had decided to appoint a committee to consider the present law relating to the adoption of children and to report whether any, and if so what, changes in policy or procedure were desirable in the interests of the welfare of children. His Honour Sir Gerald Hurst, Q C, would be chairman of the committee, and Miss J M Northover, of the Home Office, the secretary.

Surgical Boots

In answer to a question, Mr MACLEOD stated that in England and Wales during the twelve months to May 31, 1952, 48,071 pairs of surgical footwear were issued, costing approximately £400,000. In the seven complete months since then 19,435 pairs had been prescribed.

Pneumoconiosis Benefits

Dr BARNETT STROSS asked the Minister of National Insurance whether he would make a statement concerning the pneumoconiosis benefit scheme giving, to the nearest date, the number of applications made for benefit, the number of cases examined and still outstanding and the number receiving benefit following examination.—Mr R H TURTON replied: The following is the information asked for:

PNEUMOCONIOSIS AND BYSSINOSIS BENEFIT SCHEME 1952

(Period from March 10, 1952 (commencement) to Jan 3, 1953, inclusive)

—	Total disablement	Death	Total
Applications received	5586	860	6446
Claims allowed	2179	458	2637
Claims disallowed	2153	237	2390
Claims under examination	1254	165	1419

Obituary

GEOFFREY DOUGLAS HALE CARPENTER

M B E, D M Oxfd

Professor Hale Carpenter well exemplified a pecu British product, the doctor naturalist who allowed w was at first a hobby to become the pivot of his ca In this respect he was a disciple and follower of Edward Poulton, and Oxford with its traditions be his spiritual home. He was not entirely bound entomology and it was his understanding of all for wild life that brought him international fame.

Hale Carpenter was born at Eton 70 years ago and received the main part of his education at Oxford zest for entomology was inherited from his fath master at Eton, who was also a distinguished natur and a fellow of the Royal Society. Having chos medical career he took a second-class honours de natural sciences from St Catherine's Society, Oxford 1904. With a university entrance scholarship he th entered St George's Hospital, where after qualifying 1908 he served for a year as house-surgeon and h physician.

In 1910, on entering the Colonial Medical Service studied tropical medicine at the London School Tropical Medicine under Sir Patrick Manson and C Daniels. It was this experience that decided his fu for almost immediately after obtaining the certi of the school with honours, he was appointed to th Royal Society's Sleeping Sickness Commis Uganda. At Entebbe he found his true métier in th stimulating company of Sir David and Lady Br Harvey, Mackie, and Hamerton, who had joined to in the great research on the relationship between tryp somes, tsetse flies, and the magnificent mammalian fa of Central Africa. Carpenter's special attention directed to the tsetse flies; but in his researches on th habits he studied reptiles and crocodiles as well. Du the 1914–18 war he served as a medical officer in E Africa.

In 1920 he was appointed special officer in charge the sleeping-sickness campaign in Uganda. He was th obvious choice for the post, for which he was fitted b inclination, training, and experience. His reputatio may well be judged by the results he obtained, for it largely due to his work that trypanosomiasis is no lo a scourge there. This appointment ended in 1930 wh he retired from the Colonial Service.

The following year found him in Ngamiland, at th extreme northern border of the South African Un where in the Okavango and Chobe swamps a foc human trypanosomiasis (*Trypanosoma rhodesiense*) h been discovered and where tsetse flies (*Glossina mors* abounded. Returning to Oxford he was appointed H professor of zoology (entomology) in 1933. Hav entered this academic career he was little seen in med circles, but during the late war he lectured on tro medicine to troops stationed near Oxford.

His many scientific publications were mainly on th entomology and the bionomics of tsetse flies, but he w greatly attracted by the phenomenon of mimicry butterflies, moths, beetles, hornets, and other in and he quoted examples also in birds. In 193 published a monograph on this subject. Two pop books of his, which contain a wealth of information *A Naturalist on Lake Victoria* (1920), and *A Natur in East Africa* (1925). As a speaker he was much so after, for his addresses had an appeal, in their dive and interest, far beyond mere entomological stu During these years he often visited London to attend th meetings of the various zoological and entomolo societies. He served as vice-president of the Linnea Society (1935–36), and as president of the Royal Ento gical Society (1945–46). After he retired from his ch in 1948 he spent more time than ever in his garden Cumnor Hill. He died on Jan 30.

Professor Buxton writes: "His many friend remember Hale Carpenter for his charming, enthusi manner and his very wide interest in natural hi It was this that led him to seek work in Uganda in 19 soon after he qualified. He was an excellent choic what was wanted was a doctor to study the distributi of sleeping sickness around Lake Victoria, and

ne[9] showed that the histamine content of the skin
creased 200 times by adrenalectomy. Staub[10]
ves that adrenaline and histamine are partners in a
pensatory mechanism which regulates the blood-
sure. The prompt response of many forms of
ergy to adrenaline injections confirms in a practical
the importance of this cutaneous barostat.

TREATMENT

early the treatment of urticaria is not a matter of
g an anti-histamine drug, and if that fails trying
her. Rational treatment must be based on a search
a specific antigen and for a possible connection
veen the urticaria and the patient's attitude to
ts. If the patient feels that the last straw has fallen
ome way on his back, this straw may, in his mind's
loom as large as a lash that weals his back.

einberg,[11] dealing with common misconceptions in
treatment of allergic conditions, said that although
-histamines may show their greatest effect in urticaria,
nany severe cases and in certain stages of urticaria
are by no means helpful; and they have no effect
ome people, even with the mildest type of manifesta-
Most anti-histamine drugs are powerful local
sthetics, and the anæsthetic and adrenergic effects
independent of the anti-histamine activity.[12] They
y act by blocking antigen-antibody junctions or, as
lerat[13] believes, by displacing tissue histamine from
cell receptors and liberating it into the blood, where
is partly adsorbed and detoxicated by the cellular
nents of the blood, and partly neutralised by
ulating anti-histamine.

istaminic antigenic urticaria may respond well to
i-histamine drugs, but adrenaline, the best of all anti-
tamines, is still the most valuable remedy in the worst
es. It is essential to remove the source of antigens if
ssible—whether drug, food, or the products of micro-
ganisms. Until this has been done, the anti-histamines
uld be regarded as palliatives. In drug urticaria—
e to penicillin, for example—the wealing may persist
a time in spite of the withdrawal of the drug, and
ti-histamines are especially useful in these circum-
nces.

If the urticaria seems to be of cholinergic autonomic
igin, the anti-histamines are likely to give disappointing
sults (though they may relieve irritation), for anti-
stamines are usually ineffective against acetylcholine.
hese drugs are used today as much for their antipruritic
operty as for their anti-histamine effects, but the doctor
ho uses them in this way should do so deliberately and
t deceive himself by imagining that their palliative
fect is due to their action against histamine in patients
ith non-histaminic or only partly histaminic urticaria.

The anti-histamines may relieve the irritation but
ot the wealing in pathergic autonomic urticaria, but
milar or better results may be obtained by hypo-
alamic sedatives of the barbiturate group. Some
lief may also be obtained for these patients by a
orning dose of amphetamine sulphate to encourage
he release of emotional tension through action or
ords.[14] Rest, although theoretically indicated, is of
o certain value in chronic urticaria, and, after all, it only
elieves a secondary cause. These measures are merely
alliative and symptomatic, in the same way that the
se of anti-histamines in histaminic urticaria is palliative
f the source of antigens is not removed. Lasting relief
an only be expected from exorcism and abandonment
f the morbid fantasies.

In England Now

A Running Commentary by Peripatetic Correspondents

According to Professor Konrad Lorenz,[1] whom we were all happy to welcome to London this week, the present remarkable relationship of man and dog goes back to the time when dogs joined wandering tribes of primitive huntsmen as scavengers of any surplus mammoth flesh. After a few generations the dogs began to pay for their board by acting as guards and hunting aides. Ultimately some dogs ceased to be capable of living independently and came to accept Man as a substitute for their pack-leader—a healthy symbiosis which survives to this day in most homes of suburban England. But though Lorenz has illuminated many facets of dog behaviour, personal experience of three charming but quite diabolical dachshunds has convinced me that there is much about dogs that has yet to be explained.

George, the ringleader of this unholy alliance, whose mother came from Bangalore, presents a baffling and often sinister pattern of behaviour, part intelligence and part instinct, which is quite beyond me, a mere doctor, to understand. At the age of 18 months he has succeeded in becoming a master of overdogmanship; for example, he always goes rabbiting with his younger colleague and returns smooth and shiny, not a hair out of place, carrying a rabbit, while his companion, who is covered from head to foot with mud and is clearly regularly employed as a ferret, trots humbly behind, hoping he may be allowed perhaps a mouthful. And yet they appear to be on the best of terms; students of political philosophy may be able to explain this.

The other evening George resented a delay in his meal, and was found, five minutes before our guests arrived, standing in the middle of our carefully contrived dining-table décor licking the polished glasses, which activity he forsook, on our approach, to stare coldly past us. Considering his length of leg and the height of the dining-table, we considered this a remarkable physical as well as intellectual feat.

During a scuffle in the kitchen the youngest dog secured and triumphantly, if slowly, consumed a teat from the baby's bottle. George's rage and frustration were wonderful to witness; he made his observations, planned his crime, and awaited his opportunity; and nine days later, when the appropriate drawer was inadvertently left an inch or so open, he secured a brand new teat in 'Cellophane' wrapper. His happiness was complete, and we wonder what Dr. Freud might have made of this. I feel that this particular human tribe must soon accept George as its pack-leader; it could perhaps do worse.

* * *

WHENAS IN SULKS

"I've had a quite magnificent idea,"
Said Robert Herrick. "I have asked Anthea
—A charming girl with poise and no boloney
I always think; I've also asked Oenone,
Electra, Dianeme, and Corinna,
And all those rosebud-gathering girls to dinner.
I wonder if we ought to ask Perenna?
She doesn't look so well with all that henna . . ."
He faltered, smiling nervously at Julia,
Observing that she looked a shade peculiar.

* * *

"I'm just going to Capetown." "I'll see you in Montreal." Such words are heard in the main corridor of my hospital probably even more often than at a large airport. All this is because the names of Commonwealth cities have replaced numbers for labelling the wards. The change, though no doubt a broadening influence in our life, is not all gain, for the numbers indicated geographical location. Thus the three floors at the north end of the hospital were North 1, North 2, and North 3, and the small ward attached to the lower ward was generally called "North 1 little end." The two floors of the medical block are now Durban and Capetown. It would have been easier if Capetown was ing services general surgery, general medicine, ophthalmology, otorhinolaryngology, orthopædics, pædiatrics, obstetrics, gynæcology, outpatient, laboratory, pharmacy, and radiology Special facilities are provided as follows neuropsychiatry, Burderop Park, urology, Burderop Park and South Ruislip, orthopædics, Burderop Park, cardiology, South Ruislip, allergy, Wimpole Park A mortuary service is provided at each of the four hospitals, or information may be had from the nearest American station Any doctor wishing to use these arrangements for the investigation or treatment of American patients should get into touch with the appropriate hospital or the nearest hospital

A STUDY OF CHILD DEVELOPMENT

In 1951 a long term study of the physical and mental development of normal children, from birth to the end of adolescence, was begun by the Institutes of Education and Child Health of the University of London The investigation now has a sample of about 100 babies, who are seen at regular intervals Expectant mothers (and their husbands) are interviewed during pregnancy, and are asked to cooperate by bringing their babies to the child study centre at the Foundling Hospital, Coram's Garden, Brunswick Square, W C 1, and by receiving research workers in the home Few parents have refused to help, and it is planned to take in further samples at intervals, until the total number of children is about 250,

At each visit to the centre, the mother is interviewed about the child's health, experience, and behaviour, since her last visit She is asked about the kind of routine she follows for feeding, sleeping, elimination, for example, and the child's reaction to it, about the child's level of development in locomotion, manipulation, speech, and imitation, and about early signs of temperament and personality as evidenced by behaviour with strangers, readiness to cry, and responses to different members of the family Objective tests and observations are also made and a full clinical examination is made As the children grow older note will be taken of school progress, and its relation to earlier stages of development

INDIA'S HEALTH PROBLEMS

Under the new constitution the 28 States of the Indian Union control their own public health programmes The central government acts in an advisory capacity in furthering progress through national and international conferences, conducting and promoting research through national institutes, setting up uniform medical and drug standards, and training teachers for medical colleges Emphasis is shifting from curative to preventive medicine, and research is being conducted in tuberculosis, cancer, malaria, cholera, and other tropical diseases Unicef and W H O have aided greatly by providing both experts and funds Four international teams are active in anti malaria work, and Unicef has sponsored three tuberculosis centres in Delhi, Patna, and Trivandrum to train personnel, as well as prosecute research Unicef has also worked out a comprehensive plan for child welfare and maternity clinics to secure uniform sanitation and nutrition measures to lower the maternal and infant mortality rates, and to ensure the health of future citizens Both Unicef and W H O are collaborating with the Central and Bombay governments in erecting a penicillin factory near Bombay

B C G vaccines manufactured in a factory near Madras are being used in mass inoculation programmes by more than ninety teams operating throughout the country The Council of Medical Research, in collaboration with W H O, is to seek precise data on the epidemiology of tuberculosis in India, and to assess the efficacy of control measures under local conditions The Rockefeller Foundation has donated funds to the Indian Cancer Research Centre in Bombay, to meet working expenses of a laboratory for studies in human variations

Since 85% of India's population lives in villages, rural health measures are naturally receiving increasing attention The State governments are amalgamating villages in units, or blocks, to be served by dispensaries and in remote areas by mobile vans manned by a doctor and a pharmacist Moving pictures on basic hygiene and diet habits, as well as leaflets and pamphlets, are carried by mobile units. Sound track broadcasts are conducted in village meeting places The States are strengthening measures by centralising work under health officers appointed for each district They going ahead with safe water supply schemes and con of sewage plants Madras, for example, has a five-yea for rural areas, and a twenty-year project for providing and sewage plants in all towns with populations of 10 over Madhya Pradesh, Bihar, Bombay, Uttar P and Orissa are following suit, taking up the pro environmental hygiene, and furnishing piped water, dr and wells in towns and villages

To combat the serious shortage of doctors, nurses, and trained personnel, medical training facilities all over country are being expanded, and many institut following the pattern of colleges in West Bengal and Pradesh wherein "double shift" teaching systems force for the training of twice as many doctors Old p tioners are being offered refresher courses, and spec training is available for orderlies, attendants, and mid Colleges have been upgraded and given State grants, the number of yearly admissions has been stepped up.

The first attempt to raise nursing to professional s was started with the establishment of the Nursing Col Delhi, offering courses of university standard Special de in dietetics and nutrition are being awarded Also, gr schools have begun training public health engineers, pioneer in this field being the All India Institute of Hy and Public Health The All India Medical Institute in due course, provide the nation with qualified adm trators in medical and allied professions It has f for postgraduate research linked with the Council of Me Research

National standards are being laid down for the pr of nursing, pharmacy, and dentistry Industrial labour enjoys the advantage of medical service, coupled with benefits through the new employees' insurance act provident funds The central health ministry is now w on measures for a pure food and drug law

TELLING THE LAYMAN ABOUT MALARIA

The subject of malaria is so overloaded with techn terms that it taxes the wisdom and memory of even the m earnest student Prof George Macdonald[1] has pre an up to date, clear, and concise account of this so constructed and phrased as to be intelligible to th reader This is a difficult undertaking in which he succeeded admirably, it will be read with pro sanitarians, planters, miners, and others The epide logical types of malaria are discussed, and the condi and mosquito carriers in some selected areas described principles of malaria control are set forth, whilst over pages are devoted to residual insecticides Finally there two appendices—one dealing with the malaria parasite a the other with mosquitoes—couched, as far as possib unscientific language and illustrated by outline figures

A MEDICAL MISSIONARY

Reared in Illinois, the son of a Congregational minister, James McCord had, from boyhood reading of the travels of Livingstone and Paul Du Chaillu, been fired with the ambi to go to Africa His plans to achieve this by becoming missionary were nearly frustrated by his shyness and ina to preach, but his future wife suggested that he might as a medical missionary, and this he eventually did[2]

He landed at Durban in 1899 with his wife and two sm children, and his book gives an interesting picture of a med missionary's life up country He had to learn the Zu language and win the confidence of the natives, who w accustomed to the crude methods of their witch-doc He found that the more nauseous a medicine was, the more Zulu patients would believe in it and benefit from it, i then resembled most closely the magic remedies the wi doctor dispensed The appalling suffering and loss of l especially of mothers and young children, resulting from t natives' ignorance, and their exploitation by the crafty ignorant witch doctors, is graphically described

Later on, Dr and Mrs McCord moved back to Durban eventually—in the face of bitter opposition from some of ditions. (In many villages, for example, the surgery often far more suitable than the hired room in the ish hall which houses the clinic.) The main point to put the responsibility for child health where it ongs—with the family doctor.

ANDREW SMITH.

SIR,—In 1944 the late Dr. Dalrymple Smith, of chmond, and I wrote a memorandum on the care of e child in the future health service which was almost ntical with the suggestions of Dr. George and his lleagues except that we carried the care back to e antenatal period. Since we wrote that, I have come convinced that such an association of general-practioner pædiatricians (or, as we called them, family actitioners) with a group of general practitioners would feasible only in the group practices of small market wns, where 4–8 practitioners cover the whole area. In ral areas and in densely populated urban areas (where ere seems little tendency toward the *spontaneous* rmation of group practices) I am sure that the general actitioner should become the family doctor and give th preventive and curative advice.

If we split up the life of "the whole man," the doctors tending him in the different phases will never learn how e care or lack of care of the infant and the child can fluence the future well-being of the adult. Faulty advice d unsuitable treatment may be perpetuated by the ilure to recognise its effects. Such a situation arises ready with regard to advice on infant feeding given by ersons who never see the baby after the first few weeks. ack of knowledge of the subsequent failures leads to mplacency and rule-of-thumb methods.

Another point that it would be well for us to remember that it is not the practitioner who treats the child, but he mother. I am sure that there are many doctors who re "interested in children," and give much thought to heir diagnoses, lines of treatment, and prognoses, but who fail utterly to gain the confidence of the mothers. This is usually because they give them orders, instead of nviting the mothers to observe the children for them. The best way of gaining the confidence of mothers is to know them well before and during the time their babies are born.

The best way to ensure happy and thoughtful parents for the next generation is to follow our present patients carefully from childhood through adolescence to manhood and womanhood.

York.

F. CHARLOTTE NAISH.

SIR,—I hope that Dr. Tabbush's suggestion that general-practitioner services should be split up on an age-group basis at a point halfway through childhood will not be seriously entertained. His justification of this attack on the "concept of the family doctor" appears to rest solely on the statement that in certain families different members of the family are looked after by different doctors already.

It would be a bad mistake to assume too lightly the inevitability of the defects of the past and present, and to make administrative arrangements which would ensure their perpetuation. The present division of responsibility for the health of children between general practitioners, child-welfare services, school medical services, and hospital outpatient departments is such a defect. This encroachment on the responsibility of the family doctor is to a large extent the result of the failure of the old National Health Insurance system to cater for dependants of bread-winners: many parents could not afford to pay private fees, and children therefore got no medical care unless ill enough to warrant a visit to an outpatient department or admission to hospital; and general practitioners thus lost much of the experience they would otherwise have gained in dealing with childhood ailments and problems. The child-welfare services grew up in an attempt partially to fill this void; but when in 1948 a universal medical service, available to all citizens of and visitors to this country was introduced, the opportunity arose of filling this void more satisfactorily from another direction. Since 1948 there has been no particular economic reason why children should not receive all the medical care they require from the family doctor; but habits change slowly.

It has been my experience, when working in a children's outpatient department in London, that we spend much of our time dealing with problems which need never have been the subject of a consultation if the family doctor had had the time, the inclination, and the opportunity to observe the symptom in its home environment. In these outpatient sessions we hear many of the criticisms of our colleagues in general practice to which your correspondent refers: but this is not a matter solely of the extent of these doctors' specialist knowledge of children's diseases. If a doctor has failed to give satisfactory service to a child, the same has usually applied to his dealings with adult members of the family: but we most of us tend to worry more about our dependants, and especially our children, than about ourselves; and a responsible parent who is thus dissatisfied will immediately seek whatever other help is available, whether in a welfare clinic or in a hospital outpatient department. But these are second choices; everybody's first choice would be a responsible doctor, proud of his job of looking after the whole family.

The attitude to medicine which sees nothing fundamentally wrong in the splitting up of general-practitioner services by age-groups will, if applied in other fields, lead directly to a service in which the general practitioner ceases to hold the major responsibility for the health of the family, and acts solely as an agency for a variety of narrow specialties; and to a state of affairs in which the patient only gets satisfactory service to the limited extent that he is a machine which develops remediable mechanical faults. Surely the ideal service is one in which the patient's contact with specialist branches of the profession is solely through a responsible family doctor by whom opinion is sought and to whom opinion is given, as has always been the case in the best private practice. Like all ideals this is not universally attainable, but it is none the less worth striving for. We shall not approach it by throwing it overboard.

All of us who work for children wish to do our best by them, but we must look carefully ahead; and I am sure that your correspondent has not seen the precipice over which he would lead a Gadarene herd.

In our maturing health service only the continuing personal service, which the family doctor alone can give, can protect the patient from what most of us regard as a characteristic evil of our time, but which is probably universal, and which was certainly sufficiently well recognised by critical observers of the first Elizabethan age for Shakespeare to describe it for all time as "the insolence of office."

DAVID LAWSON.

SKIN BANKS

SIR,—Prof. L. S. Penrose has recently drawn my attention to Mr. M. F. A. Woodruff's reply[1] to my letter.[2] Mr. Woodruff has raised some arguments which I must admit do seem to be cogent, suggesting that the number of independent skin antigens in man is unlikely to be as low as 20. Nevertheless I think it would be a pity if the criticism of my letter were to obscure the points that are uncontroversial. The general theoretical results could be applied to any homografting or homotransplanting work in animals or man. It is also worth noting

mined by the technique adopted by Gilmour[7] for parathyroid in man or that of Platt[2] in the dog. ed Stoeltzner[8] many years ago in his "adrenal ry" stated that disease of these glands was a cause steomalacia. At one time it was also said that in hypertrophy of these glands was observed in nic nephritis.[9]

arwick. A. H. HOGG.

TUBERCULOSIS MORTALITY

IR,—In your leading article on this subject (Jan. 24) have misrepresented a statement in my paper.[10] a say:

> "Russell states that previous investigations based on the ohort method of study have emphasised the dependence of ulmonary tuberculosis mortality in adult life on that xperienced by the same age group in childhood."

iat I actually wrote was:

> "The conclusion reached by previous cohort investigators s that the magnitude of the phthisis mortality in adult ife is shaped or determined to a greater extent by the onditions of life in childhood than by happenings in or bout the year of death."

As regards your later comment on the influence of ildhood environment on adult phthisis, I would say at according to the Kermack theory one would expect continuance into later life of the high positive correion shown to exist up to age 25. As will be seen in ble IV, the association disappears and the correlation th contemporary environmental conditions becomes finitely the more important.

Institute of Social Medicine, Oxford. W. T. RUSSELL.

PSYCHOSIS WITH ISONIAZID THERAPY

SIR,—I wish to report the following case.

A man, aged 26, and weighing 48 kg., was admitted to iad Hospital on Dec. 11, 1952, with bilateral caseo-pneuonic tuberculosis. He was given isoniazid ('Rimifon') in daily dosage of 6 mg. per kg. body-weight, with streptoycin 1 g. every other day. His condition improved greatly; s appetite was always good, though he complained of odominal pain, constipation, and drowsiness.

On Jan. 14, 1953, he developed mental symptoms. He as very irritable and had hallucinations and delusions. ometimes he cried and put his hand on his head, and later ll into a confused muttering and impulsive movements. xamination showed exaggeration of the tendon reflexes; he cerebrospinal fluid was normal. There were no skin, ral, or gastro-intestinal manifestations of pellagra, but ince it seems that isoniazid inhibits the action of nicotinic cid in the formation of co-enzymes necessary for cell etabolism, we decided to stop isoniazid and to give icotinamide.

Administration of nicotinamide was started on the same ay with 100 mg. intramuscularly and 50 mg. by mouth every hours. By the 3rd day the patient's condition had greatly mproved, and on the 4th day he was completely cured of his sychosis: he was quiet, and his reflexes were normal; his appetite was good, and he no longer complained of abdominal pain or constipation.

This case, together with that described by McConnell and Cheetham,[11] proves that isoniazid in a daily dosage of 6 mg. per kg. is not always without ill effects in an undernourished patient who is not given enough nicotinio acid to balance the action of isoniazid. Nicotinamide should be given in such cases to prevent the organic cerebral impairment described by Hunter.[12]

Riad Hospital, Riad,
Soadi-Arabia.

M. ZABAD.

THE ANKLE BLOW-OUT SYNDROME

SIR,—I also would like to congratulate Mr. Cockett and Mr. Elgan Jones on their excellent article of Jan. 3. It is outstanding as a contribution to the literature about leg ulcers because it consists mainly of factual observations. Mr. Krafft's letter (Jan. 24) is not so well founded on fact, but his opinions and theories have their value. Previous correspondence on this subject has shown that many agree with him that firm bandaging will allow an ulcer to heal, and I would like to ask Mr. Cockett whether he could record the pressure in the veins below, beneath, and above such a bandage, and thus supply Mr. Krafft with more facts on which to base his theories.

Alnmouth, Northumberland. G. L. LEATHART.

SIR,—It is extremely unfortunate that Mr. Krafft should have read in the paper by myself and Mr. Elgan Jones statements which are not there! We do not claim that an incompetent perforating vein or veins is the cause of every ulcer. Nor did we say anywhere that incompetence is always found only in the perforating veins in cases of post-thrombotic ulcer. Such a statement is obvious nonsense.

In drawing attention to this particular site of venous valvular incompetence it is important to realise that it may be, and often is, a part of a much more extensive incompetence in the leg. It may be associated with post-thrombotic valve destruction in the deep veins of the calf or of the whole length of the leg. The anatomical path by which clot in the calf veins may find its way into the perforating vein, and thus cause this particular local venous incompetence, was pointed out in the last part of our paper, and has been observed several times since. For this reason we would expect incompetence of the perforators to be a fairly constant result of deep vein thrombosis, and this we have in fact found. Now in these legs with extensive valvular destruction in the deep veins from ankle to groin, due to old femoral thrombosis, the ulcer is only one component of the post-thrombotic syndrome; the other two components are postural œdema, and postural pain and aching in the lower leg. Our experience of the results of deep-vein ligation (extending over about 20 cases to date) has been reasonably clear-cut. The aching in the leg is always relieved; the swelling is often improved, but is never made worse; the ulcer is seldom affected much. If the swelling is made worse by deep-vein ligation, then probably a competent vein has been tied in error. One of the great difficulties in this work so far has been the lack of a simple, easy technique for showing for certain whether valves are present and functioning in the femoral vein. This difficulty has been met by the introduction of the Valsalva technique of venography. (This technique is shortly to be described in the *British Journal of Radiology*.) Thus it was this notable failure of deep vein ligation to control ulcers which set us looking for a more local cause underneath them. Moreover, well over half of our ulcer cases show numerous competent valves in the femoral vein at venography. To argue that, in spite of the valves being there, they are perhaps not as competent as they should be seems to us to be begging the question.

Finally there are a small group of cases in which an incompetent perforating vein draining into a mass of dilated venules beneath the ulcer is the only venous lesion demonstrable in the limb. This was so in the case dissected and described in our paper; and we have had several fully investigated cases since then, which have been operated upon. To suggest that such a state of affairs can have little to do with the ulcer, and to base this solely on a complicated mechanistic theory of action of the calf pump, seems to us inadmissible. Mr. Krafft overlooks the vital point in the structure of the calf pump—namely, the fact that it is a large muscle within

12. Hunter, R. A. *Ibid*, p. 960.

this theoretical principle In the first four days of salt depletion, his subjects lost weight in parallel with their loss of sodium, indicating that the osmotic pressure of body-fluids was being conserved at the expense of volume Later on, however, the body-weight fell only slowly, while the sodium-loss continued, so that the serum sodium fell In clinical salt depletion, the serum-sodium is usually low, indicating a rather advanced sodium depletion, we shall discuss later the bearing of this fact on therapeutic methods

Although the volume of extracellular fluid can be plausibly related to the osmotic activity of its sodium and associated anions, evidence has accumulated of serious deviations from osmotic equilibrium within the body Analysis of cell fluid shows a higher concentration of base than in the extracellular fluid, which led Peters (1947) to postulate the existence of " osmotically inactive base " within cells, Elkinton et al (1948) have accepted this concept, and brought forward evidence of discrepancy between shifts of cation and of water across the cell wall, suggesting that the proportion of cell base which is inactive may change from time to time A more radical approach is that of Robinson (1950, 1952), who discards osmotic determination of body-water distribution in favour of a continued active process of water extrusion from cells, which keeps the intracellular osmotic pressure consistently higher than that in the surrounding medium Robinson showed that tissue slices would remain in equilibrium with " isotonic " media only so long as their oxygen uptake was normal, when metabolism was depressed by cyanide or by oxygen-lack the cells took up water even from " hypertonic " solutions up to an osmolarity of 0 58 osmols per litre Similar active transport mechanisms are invoked by Ussing (1952) to explain the low sodium content of cells in a medium of high sodium content such as extra cellular fluid The active expulsion of sodium ions sets up a potential difference across the cell wall, and the high potassium content of cells can be attributed to a passive flow down an electrochemical potential gradient Terner, Eggleston, and Krebs (1950) have shown that brain tissue maintains its potassium content in a saline medium containing oxygen, glucose, and L glutamate, if any of these is missing from the medium, potassium leaves the cells, returning when the missing item of substrate is restored The lower sodium and higher potassium content of fœtal, as compared to maternal, erythrocytes in the sheep, has been related to the more rapid glycolysis and greater oxygen consumption of the fœtal erythrocyte (Hallman and Karvonen 1949) These examples may illustrate a tendency to explain apparent anomalies of body-fluid distribution and composition in terms of active processes, dependent on the energy of tissue oxidation, rather than in terms of classical physiochemical equilibria The final balance between these modes of thought has certainly not yet been struck As William James says in another context, the sciences " habitually advance by zig-zagging from one absolute formula to another which corrects it by going too far the other way "

Regulation of Body-fluid Tonicity and Volume

Although the composition of body-fluid is both complex and variable from one phase to another, it is possible to find evidence of a control of the general parameters of body-fluid which transcends the detailed operations on separate ions and molecules There is a suggestion from McCance's experiments that osmotic tonicity is more jealously guarded than the volume of body-fluid, and this is borne out when we consider the characters of the regulatory processes which normally govern body fluid It is a fair generalisation that the body reacts quickly to stimuli which modify the tonicity of body-fluids, but more slowly to those which modify volume without change in tonicity, this is perhaps best shown by the very different response of a normally hydrated subject to water and to 0 9% salt solution An increase in body-fluid tonicity stimulates both thirst (Wolf 1950) and the output of posterior-pituitary antidiuretic hormone (A D H) (Verney 1947), a decrease in tonicity inhibits thirst and A D H output Both responses are rapid, and the excess water load is eliminated, or the deficit made good, within an hour or two Neither response, at least in man, need involve any change in the solute content of the body This close and rapid regulation of osmotic tonicity implies that changes in the volume of body-fluid shall be attended by corresponding changes in the total solutes of the body, except in so far as intracellular solutes may gain or lose osmotic effect or have their osmotic action overborne by change in intensity of active shifts of electrolytes and water For the present, we may be justified in accepting changes in sodium balance as representing changes in osmotically active solute If we do this, we gain the impression that control of the volume of body-fluid is much less close and rapid than that of body tonicity For one thing, expansion of the volume of body-fluid by saline provokes only a slow and incomplete diuretic response, unless the subject has been preconditioned by a water load, in which event he has a water rather than a saline diuresis (Ladd 1950) Moreover, on a diet of constant sodium content, and with minimal sweating, the sodium balance shows quite wide fluctuations, the equivalent of as much as a litre of body-fluid (Black and Thomson 1951) If one can assess the sensitivity of a regulating mechanism in terms of permitted percentage variation in the quantity regulated, it would appear that the regulation of tonicity, at least by the A D H mechanism, is considerably more sensitive than the regulation of extracellular fluid volume, the phase of body fluid most directly related to the sodium balance The A D H mechanism is sensitive to a change of about 1% in the tonicity of the blood supplying the hypothalamus (Verney 1948), whereas variations of the order of 6% of extracellular fluid or 2% of body-fluid, are accepted, without immediate response, by the mechanism regulating volume

It may not be altogether a coincidence that we know a good deal of the regulation of tonicity, whereas that of volume largely eludes us A rapidly acting mechanism can be studied by short critical experiments, whereas a slowly acting mechanism, especially if it is bedevilled by diurnal variation (Stanbury and Thomson 1951), yields its secrets more reluctantly, and with greater chance of random error I do not know if this is a valid reason, or merely an excuse, for the collective failure of natrophiles to expose a mechanism of regulation comparable in elegance to the A D H mechanism, it may be that we still await our Verney The essence of the problem clearly lies in the regulation of output of sodium and potassium in the urine, for there is no evidence of any intake regulation of these ions comparable to the thirst mechanism for water I have lately reviewed the factors which determine sodium excretion (Black 1952), and shall now merely reiterate the conclusions that variation either in glomerular or in tubular activity may be critical under different conditions, and that the body possesses efficient mechanisms of sodium conservation, which is mainly effected by enhanced tubular reabsorption of sodium We do not clearly know what change in body fluid composition or distribution triggers off this mechanism, nor indeed anything of the way in which the message reaches the tubule cell Adrenal hormones are known to increase sodium reabsorption in the renal tubule, but definite evidence of their participation in the normal response to a low salt diet is still lacking The regulation of potassium excretion has been reviewed in some detail by Berliner (1950), here again we are far from understanding the mechanisms involved On a

TMENT OF PNEUMOCOCCAL MENINGITIS

—I have read with interest the article by Dr. and Dr. James.[1] Excluding 3 deaths within y-four hours of the start of treatment, they have ed a recovery-rate of 100%.

experience in Nyasaland has been very different.

e April, 1951, I have had 10 cases of pneumococcal gitis under my care; 6 were in children between d twelve years of age, the remainder being in adults. had only 2 recoveries, 1 a child and 1 an adult. ent consisted in a daily intrathecal injection of units of penicillin with 100,000 units intramuscularly rly. This was supplemented with 'Sulphatriad' or diazine 1 g. four-hourly after an initial loading dose. ese patients had been ill for three or four days before g to hospital. They usually improved at first; but a week the theca became blocked, and in 2 cases llin was administered by cisternal puncture with no vement.

ave tried intrathecal streptomycin and oral chlor-enicol with no better results. Up to date I have no means of improving on our 80% mortality-rate. r as I am aware, most doctors in Central Africa had similar experience; and Dr. E. R. Cullinan, recently visited Nyasaland, informed me that he gained the same impression in other parts of Africa g his tour as Nuffield visitor.

ave never given penicillin in as large a daily dosage 1,600,000 units used by Dr. Gibson and Dr. James. ld not like to increase the intrathecal dose, as even 50,000 units convulsions have occurred.

rican Hospital,
ba, Nyasaland.

J. W. D. GOODALL.

SEARCH FOR SICKLE-CELL TRAIT

s,—I read with great interest the article by Dreyfuss and his colleagues[2] on the search for sickle-rait in Yemenite Jews.

few months ago I had the same difficulties that these stigators describe. Using the moist stasis method criver and Waugh[3] I investigated more than 200 nesian patients (taken at random from the General ral Hospital at Djakarta). Of the 216 patients nined in this way, 2 were found positive for sickling he blood. Moreover, a private patient of mine with ominal crisis was also found positive.

ssuming that the method of Scriver and Waugh was ific and that a positive result indicated a sickle-trait or sickle-cell anæmia, I believed that I had d the sickle-cell trait in Indonesians. However, her examinations of the blood of the same patients e inconsistent results. Sometimes I obtained positive lts and at other times negative results in the same ients. I have since found more positive tests for ling with the same lack of consistency.

s a routine all the slides to be used were cleaned in romate/sulphuric-acid mixture for two days, then washed unning water. They were then placed in distilled water twenty-four hours and finally transferred to absolute hol, where they remained until use.

n one occasion I used a batch of slides which had been ated as described above except for the cleaning with omic acid. This batch of slides gave many positive results h blood of different patients taken at random from the spital. However, using another batch of slides these ne patients gave negative results. I collected the slides ich gave positive tests and examined my own blood on m. As a control, slides which had given negative results h the blood of the same patients were also tested with blood. All the slides which gave positive tests with the ferent patients' blood gave also positive tests with my od, and all the negative ones gave a negative result. the test-tube method of Beck and Hertz[4] my blood and that of these patients did not show sickling. Addition of ascorbic acid (2% or 5%) or bisulphite (2%) to the blood under liquid paraffin did not give sickling. Using the other sides of the slides with a positive preparation I could get the blood of all my laboratory workers to sickle. I concluded that something on the slide (a chemical substance?) caused the sickling. Sometimes the whole preparation showed a full development of the abnormal cells, but very often the sickling appeared in localised areas. The sickling usually appeared after twenty-four hours (sometimes earlier or later) but never immediately as in the test with glue.[5] It was further found that incubation was not necessary, and a positive result could also be found without sealing the preparation and without preliminary stasis of the blood.

If a slide with positive test is washed not too vigorously with water, the same slide can again give a positive test with any blood; but after vigorous washing and brushing the test becomes negative. Moreover, washing in bichromate solution did not assure that a slide would not give an erratic result.

I am of the opinion that the method of Scriver and Waugh, without control, should not be used as a routine test; for it is very difficult to be sure that a slide is entirely free from the sickling substance, which (even in traces) causes sickling of the blood of any person.

When I read the article by Caminopetros[6] on sickle-cell anomaly as a sign of Mediterranean anæmia, I suspected that the factor described above caused the sickling in most of his tests, though perhaps not in all. If so, the difference between the findings of Dr. Caminopetros and those of Dr. Choremis[7] on the sickle-cell trait in Athens can easily be understood. The same suspicion arose when I read the article by Dr. Dreyfuss and his colleagues.

A more detailed description of my investigation will be published later.

DEATH AFTER ANÆSTHETIC WITH HYPOTENSION

SIR,—Dr. Bodman's example of modern anæsthesia (Nov. 29) and Dr. Belfrage's comment (Dec. 13) suggest this question: How many such patients would be alive and well today had they had chloroform on a bit of lint? In the old rag-and-bottle days did we really kill as many as now succumb to "advances" in anæsthesia?

I have spent twenty-five years in the tropics, in Africa and on ships, where chloroform, given by an untrained nurse or dispenser, is the only general anæsthetic available; and well it serves us. Yet, I am told, there are persons with the D.A. who have never given it in their lives.

And another thing; what was the cost of all this, compared with that of a few drachms of chloroform?

G. L. ALEXANDER.

CARTRIDGE-TYPE HYPODERMIC SYRINGE

SIR,—The introduction of the cartridge-type hypodermic syringe is an obvious sequel to the use of a similar instrument in dental surgery for many years.

The method is hardly suitable for intravenous injection as the plunger cannot be deliberately withdrawn. The accidental "recoil" of the plunger following injection is well illustrated by the simple test of injecting a small amount into a bottle of ink. The quantity of ink which flows up the needle and enters the phial on the release of the plunger has to be seen to be believed.

Attention has already been drawn to this drawback in *dental journals*, for it is obvious that cross-infection could easily result if a cartridge left over from a half dose were used on a second patient.

sodium loss is limited by increased renal formation of ammonia (Gamble et al 1923) In renal disease and in Addison's disease (Jimenez-Diaz 1936), ammonia formation is impaired and acidosis may then lead to continued loss of sodium Sodium excretion may also be increased deliberately by mercurial diuretics, and this may on occasion lead to a "low salt syndrome" even in the presence of œdema (Schroeder 1949)

Abnormal Physiology

We have seen that sodium, with its associated anions, is the osmotic mainstay of extracellular fluid, and shrinkage of the extracellular fluid can account for the most significant features of sodium depletion It is true that in severe sodium depletion the osmotic standard is relaxed somewhat, permitting a fall in the serum-sodium concentration, and this may account for some clinical manifestations such as cramp and lowered intestinal motility (Streeten 1950) It is also true that the impact of sodium depletion on the extracellular fluid phase could be modified by contributions of sodium from inside the cells and from bone, but I know of no studies showing that these collections of sodium can in fact function as sodium reserves, and at present we may justifiably look on sodium depletion as exerting its main effects by reducing extracellular fluid volume Both plasma and tissue fluid are diminished in amount Hypovolæmia with reduced cardiac output leads to inadequate circulation, reflex vasoconstriction may maintain the central blood-pressure for a time, but in severe sodium depletion the blood pressure falls The vasoconstriction varies in different circulatory areas, so that cerebral blood flow is well maintained, but the splanchnic and renal blood flow are reduced to an even greater extent than the cardiac output Glomerular filtration is reduced, and nitrogen retention follows The urine usually contains only traces of sodium and chloride, not only is the amount of sodium presented to the tubules lowered with the filtration rate, but the tubules reabsorb sodium more completely The depletion of tissue fluid is clinically obvious, but we know little of its effects on function, by modifying the internal environment unfavourably, it may contribute to the increased "wear and tear" of protein which was shown in McCance's experiment by increased urea production This is speculation, and other causes for increased protein breakdown are just as likely —for example increased glucocorticoid production in response to stress, and dilution of intracellular fluid pari passu with the fall in plasma sodium which commonly attends sodium depletion

Clinical Features

The various manifestations of sodium depletion cannot be forced into a single clear-cut clinical syndrome, for they are profoundly modified not only by the primary disease but also by the concurrent state of water and acid-base balance and by the rapidity of onset and the magnitude of the sodium depletion At the cost of some violence to the facts—perhaps no greater than is commonly offered in the separation of "disease entities" from the continuum of human morbidity—we may distinguish the syndromes of acute sodium depletion, chronic mild sodium depletion, and chronic severe sodium depletion

Acute sodium depletion arises when non saline fluids are used to replace rapid losses of saline fluids, such as sweat or the exudate from burnt areas It is seen when severe exertion is undertaken in the tropics, or in comparable artificial environments Severe cramp is the outstanding symptom, and can be alleviated by ingestion or injection of salt Under tropical conditions I have seen a "salt frost" on the skin but the absolute loss of sodium in a few hours cannot equal the large losses of sodium sustained by patients with vomiting and diarrhœa, who often are free from cramp It is well recognised clinically that high water intake potentiates the symptoms of acute sodium depletion, and it probably does so by entering the cells to produce a mild degree of water intoxication (Rowntree 1922)

Chronic mild sodium depletion, as judged by moderately lowered serum sodium levels in the absence of clinical dehydration, is found in sufferers from "heat exhaustion" and from chronic wasting disease, notably tuberculosis Ladell et al (1944) described a syndrome observed towards the end of the hot season in the Persian Gulf, in which the patients suffered from loss of appetite and energy, and had low serum sodium levels, but there was no clinical dehydration, and no signs of acute sodium depletion such as cramps and vomiting They designated this syndrome "heat exhaustion, type II," in contrast to the other type of heat exhaustion observed by them in which the patients were obviously dehydrated Both syndromes improved when salt supplements were added to the diet Although low serum sodium levels have likewise been noted in chronic illness, there is no similar evidence that the low serum sodium is directly responsible for symptoms Sims et al (1950) suggest that the primary change may be a fall in intracellular osmolarity, and that the fall in serum sodium represents an accommodation to this There is no shrinkage of extracellular fluid volume, and no retention of sodium by the kidneys, addition of salt to the diet has little effect on the serum sodium level or general clinical state

Chronic severe sodium depletion is what is generally referred to, not altogether happily, as "dehydration" The term dehydration can be criticised on the grounds of ambiguity, and because it emphasises *water* depletion whereas clinical dehydration is most commonly related to primary sodium depletion, the loss of water being secondary to this Our clinical judgment of the hydration of the body is based largely on inspection and palpation of the subcutaneous tissue, whose fullness and elasticity depend on its content of extracellular fluid A primary water depletion is spread over both intracellular and extracellular fluid, whereas sodium depletion has its impact on the extracellular fluid alone, the impression of dehydration from a given degree of sodium depletion will thus be greater than that from a comparable depletion of water itself In spite of these semantic objections, the term "dehydration" does convey a familiar clinical picture, which I maintain is that of severe sodium depletion Its features have often been described, and are well recognised I do not propose to conduct you once again over this well trodden road, but rather to bring forward evidence that the magnitude of the sodium depletion which underlies clinical dehydration has often been underestimated, and in consequence sodium replacement has been inadequate I shall first consider the methods at our disposal for assessing sodium depletion

Assessment of Sodium Depletion

We may distinguish between prospective and retrospective methods of assessing the depletion of sodium, or indeed of other bodily constituents The prospective method, in which we measure the negative balance of sodium as it accumulates, is obviously only applicable in experimental studies, in which we can assume a normal initial sodium household, and can observe the induced distortion from its beginning The errors of this method are limited to those inherent in balance technique Retrospective assessment of depletion involves the measurement of the positive balance of sodium, or other substance, which accomplishes repair of the depletion The validity of this method depends on the assumption that a normal state has in fact been reached at the conclusion of the observations, an assumption which may not hold where repair of a depletion has been accelerated by giving supplements of the defective material For ologist to investigate the biology of the tsetse fly *na palpalis*. He was able to do both and to show ne disease occurred in villages that were close to the of woodland in which the insect bred: but if there n area of grass and reeds without bush between llage and the Lake, then sleeping sickness would be even though the odd fly could be found among the . He was never idle: in his spare time he made s of Central African butterflies, and on insects which dible or not, as tested on pet monkeys. In between and in the latter part of his life he became an nely skilled gardener."

e Carpenter married in 1919 Amy Frances, youngest ter of J. F. Thomas-Peter. There were no children.

Mr. S. A. COURTAULD

Courtauld's death on Jan. 28 brings to mind his benefactions to research and education, especially gh the Middlesex Hospital.

interest in this work was aroused by his association he late Dr. Campbell Thompson, who was dean of the al school during the 1914–18 war. Campbell Thompson cceeded by Mr. A. E. Webb-Johnson, now Lord Webb-on, who early recognised that the future of the London al schools lay in their association with the University ndon, and was therefore at great pains to obtain endows for university chairs in the key subjects. One of ourtauld's first benefactions was to endow the chair of my, after which he gave a sum of money to encourage ewly founded department of biochemistry, then housed e Bland-Sutton Institute of Pathology. In the early biochemistry was expanding very rapidly, and the of the Middlesex Hospital Medical School saw that ew department could not permanently be housed in the l-Sutton Institute. Mr. Courtauld provided a further antial sum of money to erect the Institute of Biochemistry, in June, 1928, the institute that bears his name was ed.

is building, composed of five floors, provided the n-needed space for extension of the department. Many e time thought it far too big to be associated with a ital, and fears were expressed as to whether its accomation would ever be put to full use. But today it is ded and indeed has recently been considerably extended hat the equivalent of practically another floor has been d. The accommodation is still inadequate for the large ber of research-workers already in the institute and also ying for admission.

r. Courtauld's benefactions did not finish here. He owed a chair of biochemistry and before the war gave a of money to provide beds for a special unit for clinical arch. These beds were governed by quite novel regulas in that they could be controlled by one of the medical ol professors in conjunction with members of the honorary f.

o the outsider Mr. Courtauld appeared rather a distant re who made his benefactions in a somewhat impersonal nner. His main motive, however, was a desire to apply great wealth to the right causes. He thought a great l before giving money, and took the advice of his friends, ticularly that of Lord Webb-Johnson; but once having de up his mind, he would support a project of his choosing the utmost of his ability. He was a classical scholar of lliance, having published a translation of the *Odes of race* which went into several editions, and he was a mber of the Horatian Society. He also had an encyclodic knowledge of 18th-century literature.

Dr. **Clifford Beale**, consulting physician to the London est Hospital, died at his home in London on Jan. 31 the age of 101. At the end of the last century he was e of the earliest supporters in this country of the en-air treatment of tuberculosis. He was elected the fellowship of the Royal College of Physicians of ondon in 1890, and he was the senior fellow.

Births, Marriages, and Deaths

BIRTHS

AVIES.—On Jan. 22, to Dr. Winifred M. Davies (née Haigh), wife of Dr. D. M. Davies of Meadehurst, Glebelands Road, Prestwich —a son.

Notes and News

"DUAL APPOINTMENTS"

At present those doctors (such as chest physicians and psychiatrists) who are employed full time but divide their work between a hospital and a local health authority are appointed on a part-time basis to the staff of both authorities. This arrangement has not worked well in practice, and the Ministry of Health in agreement with the County Councils' Association, the Association of Municipal Corporations, the London County Council, and the British Medical Association has now suggested a different procedure.[1] Where the two jobs together make up a full-time job the Ministry proposes that instead of being employed by the two authorities the doctor should receive a full-time salary from the authority which makes the greater use of his services. The authority that pays him would then arrange to provide the other authority with certain services. In the agreement between the authorities the doctor who would carry out these services need not be named. This arrangement between the two authorities would not affect the pay of the doctor concerned.

After Feb. 6 all new appointments to these dual posts will be made on this basis. The contracts of doctors engaged on a provisional basis while these negotiations were pending should be adjusted to conform by May 1, 1953, or at the expiry of any agreed period of notice. Where the new arrangement is more favourable to the doctor the adjustment should be retrospective to the beginning of his provisional appointment. Doctors who hold appointments of this kind on a permanent basis may choose whether they will continue with their present contracts or change to the new arrangement. A committee has been set up, consisting of representatives of the B.M.A. and the employing authorities, to which doctors and employing authorities can turn for advice. It may be addressed at the Ministry of Health, Savile Row, London, W.1

A FUND FOR POLIOMYELITIS RESEARCH

Since it was founded in 1939 the Infantile Paralysis Fellowship has done much to help its 8000 disabled members. During the difficult war years the fellowship wisely restricted its work to the welfare of those who had been crippled by the disease; but it has always wished also to share in the work of prevention, and last year it felt the time had come to extend its interests. After discussions with the Ministry of Health, the Royal College of Physicians of London, and the Royal College of Surgeons of England it was decided to set up a separate body, the National Fund for Poliomyelitis Research. This body was officially inaugurated by the Lord Mayor at a meeting at the Mansion House on Dec. 17. Its vice-presidents include Sir Russell Brain, P.R.C.P., Lord Horder, F.R.C.P., and Sir Cecil Wakeley, P.R.C.S.; and Dr. Reginald Bennett, M.P., Mr. Somerville Hastings, M.S., M.P., Prof. J. M. Mackintosh, F.R.C.P., Dr. Barnett Stross, M.P., Prof. J. Trueta, M.D., and Lord Webb-Johnson, F.R.C.S., are members of the council. The aims of the fund are "to promote and finance research into the causes, cure, prevention and treatment of poliomyelitis; and research into the methods of rehabilitation of those disabled from polio." It is emphasised that the fund will only spend money at the advice of the medical profession. Donations will not be unwelcome, but anyone who sends a minimum annual subscription of a guinea will become an associate of the fund and receive reports of its work. The fund's secretary is Mr. Duncan Guthrie, 41, Spenser Street, London, S.W.1.

MEDICAL ARRANGEMENTS FOR U.S. SERVICE PERSONNEL IN ENGLAND

The U.S. Service authorities in Britain have issued the following information for the guidance of doctors attending American military personnel or their dependants.

There are four U.S. Air Force hospitals in England: (1) the 59th Medical Group, Burtonwood, near Warrington, Lancs, serving the Liverpool region (tel. Warrington 3000, ext. 1070, 1060); (2) the 5th Hospital Group Burderop Park, near Swindon, Wilts, serving the Oxford area (tel. Wroughton 391); (3) the 3rd Hospital Group, Wimpole Park, near Royston, Cambridge, serving the East Anglia area (tel. Arrington 381); and (4) the 494th Medical Group, South Ruislip, Middx, serving the London area (tel. Waxlow 4300, ext. 112, 113, 114). Each of these hospitals has the follow-these fluids in a few days are not uncommon in severe diarrhœa, paralytic ileus, and postgastrectomy duodenal fistulæ. Coller et al. (1938) measured the loss of "salt" in various patients with lesions of the upper gastro-intestinal tract. In one patient the measured loss amounted to 79.8 g., representing 1360 m.eq. If in fact it was chloride which was measured, this would be an overestimate of the sodium loss, but the article does not indicate that this was so. Similar losses of sodium can occur in patients with watery diarrhœa, in one patient with steatorrhœa the fæcal loss of sodium over twelve days amounted to 1127 m.eq. Evidence of the large size of sodium deficit can also be gained from the amount of sodium which can be given in repair of the deficit. I have already quoted a man who received 1400 m.eq. of sodium by infusion without becoming clinically or biochemically "over salted." Another patient with protracted vomiting was given 1700 m.eq. of sodium in a single infusion, without ill effect, and with a fall in his blood-urea from 152 mg. per 100 ml. to 38 mg.

---

[1] Ministry of Health Circular 3 53, R.H.B.(53)11, B.G.(53)12, H.M.C.(53)10.

An indirect estimate of the sodium deficit can also be gained from the serum sodium level, and this is of special practical value in that it can be made before treatment is begun. I would remind you that in experimental sodium depletion the level of serum-sodium is conserved for a time, and then falls when the sodium deficit becomes considerable. This fall in serum-sodium is attended by the entry of water into the cells, as was demonstrated in the animal experiments of Darrow and Yannett (1935). It might be supposed that, since sodium in the body is largely confined to the extracellular fluid, the sodium deficit could be arrived at by multiplying the fall in serum-sodium by the extracellular fluid volume. In fact, however, we must use the total body-water in our estimate, and not the E.C.F. volume, the shift of water into cells maintains the E.C.F. sodium concentration at a level which does not directly reflect the loss of sodium from E.C.F. For example, a patient who has lost half his E.C.F. sodium might be expected to have a fall in serum sodium of 70 m.eq. per litre, but the observed fall in serum-sodium is only about a third of this, since there is about twice as much intracellular as extracellular fluid. This can be expressed in another way, perhaps more directly relevant to treatment, by saying that the effective volume of distribution of injected sodium approximates the total body-water rather than the extracellular fluid. In support of this contention, I have calculated the "volume of distribution" of sodium injected as hypertonic saline, using some of our own results (Black, Platt, and Stanbury 1950), and additional data provided by Dr. S. Oleesky (personal communication). When the total amount of injected sodium is divided by the observed rise in serum-sodium, we have the effective volume of distribution of sodium. In 11 subjects, this averaged 54.7 litres, with 99% confidence limits of 33.6–75.8 litres. This is not of course a practical method of measuring total body water, for the error of the difference between two serum sodium levels is high, but my point is that the average figure approximates the total body-water, and is significantly different from any possible value for extracellular fluid volume.

Entry of water into the cells is not the only factor which keeps the serum-sodium at a higher level than would correspond exactly to the sodium deficit, there is also the loss of water which inevitably attends the depletion of sodium. This is very variable from one patient to another, for although sodium is usually lost in isotonic solution, the amount of water which the patient is willing or able to drink varies. The concurrent water loss will tend to minimise the fall in serum sodium, which therefore gives a conservative estimate of the sodium deficit. In the extreme case the serum-sodium may be within normal limits, or even raised, as reported by Allott (1939), by Borst (1938), and more recently by Higgins et al. (1951). The conjunction of raised serum sodium and low sodium output is often associated with brain disease or injury, in which water intake is prevented, it is distinctly unusual in the severe sodium depletion which we are discussing. When present, it is not a contra-indication to saline therapy, if the history clearly indicates salt loss, and the patient is dehydrated. Conversely, a low serum-sodium should never be the sole indication for saline therapy, we have already mentioned the hyponatræmia of chronic disease, which is not associated with overt salt loss or dehydration, and does not respond to saline therapy, nor indeed require it.

When the clinical evidence of sodium depletion is secure, the serum sodium can be used to assess the sodium deficit, it tends on the whole to underestimate it, because of concurrent water loss. The observed serum sodium in m.eq. per litre is subtracted from 140 to give the "serum sodium deficit," which gives the amount of sodium deficit per litre of body-water. The average value of 40 litres for total body-water can be used to calculate the total deficit in milli-equivalents. This is then divided by 140 to give the number of litres of isotonic solution needed to repair the deficit. If [Na] is the serum sodium level the isotonic fluid needed is given by

$$\frac{(140-[\mathrm{Na}])\times 40}{140}.$$

Even this simple formula is too precise, and it is sufficient to take a third of the "serum-sodium deficit" as our measure of the requirement of isotonic sodium solution in litres. No one who has noted the successive approximations by which this figure is derived will be tempted to regard it as other than a crude measure of the saline requirement, but even as such it has proved itself in my experience to be of some value. For reasons which I have given, it underestimates the saline requirement, and at the completion of infusion the serum sodium is usually at the lower limit of normal. Although the amount of saline prescribed in this way may be large, I have not seen any evidence of salt overloading when this formula has been used. Others have advocated the serum chloride level or the specific gravity of the plasma as guides to infusion, but the serum-chloride level is invalidated, as a measure of sodium depletion, by acid-base disturbances, and the plasma protein level may be quite misleading in debilitated patients (Abbott 1946).

It should be noted that any such assessment can give us information only on the sodium deficit, in addition to making up the deficit, we must repair continuing losses of salt as they occur, and also cover the patient's maintenance requirement of water. When possible, the best way of dealing with continuing losses of saline fluid is to return it to the patient by stomach tube, as is done in the Hammersmith régime for anuria (Bull, Joekes, and Lowe 1949), and as can sometimes be done with the secretion from fistulæ. When the fluid cannot be returned in this way, because of its nature (e.g., watery stools) or because of alimentary dysfunction (ileus or obstruction), a fluid of similar composition and amount should be given parenterally. When the fluid loss is small, and the kidneys are healthy and well supplied with blood, volume-for-volume replacement with normal saline may be adequate. When large amounts of fluid are involved, better results are obtained by using a replacement fluid with an acidifying or alkalinising effect similar to that of the fluid lost. Short of the perfectionism of analysing the fluid, and providing a tailor-made substitute, this can be done by giving a proportion of lactate, or of ammonium chloride, in the infusion fluid. Cooke and Crowley (1952) have made a useful practical approach to this problem by devising solutions suitable for replacing ng white citizens—established the McCord Zulu Hospital, e natives were given good medical treatment, and where girls were trained as nurses. The necessity for training s in medicine, so that they might return to their own smen and help to break down the prejudice against the tific prevention and treatment of disease, led to another acted struggle with diehards among the whites; but tually, shortly before the second world war, the training ılus as medical aides who could work under the supern of white government doctors was begun.

ie book contains several colourful case-reports, including of a lithopædion and one of ruptured urethra. Dr. McCord especially interested in surgery and midwifery, and one surmise that he had considerable ability, and profited by vast experience. When he retired in 1940 at the age of nty, he left Natal and the Zulus permanently indebted to orty years of service. Throughout the book his religious fs are nowhere stated, but their effect is abundantly ent in the usefulness of his career.

versity of Oxford

n Jan. 22 the degree of D.M. was conferred on F. J. Flint Thomas Stapleton.

versity of Cambridge

n Jan. 24 the following degrees were conferred:

.D.—K. B. Dickson, A. C. C. Hughes, D. G. James, T. A. np, P. F. Lucas.

.B., B.Chir.—G. L. S. Rankin.

iversity of London

r. F. E. Bruce, M.SC.(ENG.) Lond., S.M. Harvard, has been ointed to the university readership in public health ineering at the Imperial College of Science and Technology.

yal College of Physicians of London

At a comitia of the college held on Jan. 29, with Sir Russell in, the president, in the chair, Dr. R. S. Stacey was ointed examiner in pharmacology, and Dr. D. Hunter d Dr. C. A. Keele members of the Joint Formulary Comttee. Dr. D. A. Long was appointed Milroy lecturer for 54.

The following having satisfied the censors' board were cted to the membership:

E. D. Acheson, B.M. Oxfd, Katharine M. S. Ainley-Walker, I. Oxfd, J. F. T. Allison, B.M. Oxfd, T. H. Barrie, M.B. Lond., N. Beck, M.D. Belf., Bryan Bevan, B.M. Oxfd, major R.A.M.C., mir Kumar Biswas, M.B. Calcutta, Joyce B. Burke, M.D. Lond., H. Capel, M.B. Lond., J. M. Cliff, M.B. Camb., surgeon lieutenant ., J. D. De Jong, M.D. McGill, J. E. Forster, M.B. Camb., Michael arington, M.B. Camb., E. W. Hughes, M.D. Lond., A. F. Knyvett, B. Queensland, R. C. Lewis, M.B. Lond., C. J. Lucas, M.B. Lond.

Licences to practise were conferred upon the following ho have passed the final examination of the conjoint board:

B. L. Anderson, L. P. Balfour-Lynn, R. H. Bartley, Yvonne G. eeching, Mary A. M. Beeney, F. A. F. Biddle, A. R. Bellen, M. S. Boyd, Margaret H. Bradshaw, Joan T. Bruce, Jessie A. S. D. urns, A. G. N. Calder, R. Y. Calne, H. T. Chadwick, H. W. V. harlton, Norman Crook, Agnes M. S. Curry, Sylvia J. Darke, P. H. ennison, P. G. Dunbar, W. A. Elkin, Helen R. Ellis, J. E. Evans, L. Evans, Sheila M. Forbes, R. F. Fouche, N. B. Gillison, H. R. ompertz, R. M. H. Gompertz, A. H. Gretton, M. C. Guard, ureen E. Hall, A. G. Harrison, M. D. Heyman, M. D. Hickman, E. C. ., R. J. Hutchinson, Shirley M. Inman, E. M. M. Jackson- J. A. Jemson, D. C. Jenkins, J. K. Johnson, C. G. Keith, vrence, R. E. Lovelace, K. G. Lupprian, Irene M. McAndrew, A. McClelland, H. G. McDonald, J. A. McHardy, W. M. IcIsaac, E. N. McKenzie, M. C. G. Mantell, John Marryat, Gillian G. latthews, L. J. Miller, Margaret E. C. Mitchell, G. L. Money, B. Moorhead, K. E. Murray, F. G. M. G. Myer, J. S. Norell, J. Parry, N. E. Pitts, M. F. Porter, J. F. Pritchard, Donald Ricketts, W. H. Rout, J. A. Rozario, K. E. Schmidt, Rita W. hannon, C. S. Sheldon, F. G. A. Shenton, Gurbachan Singh, John Stark, I. A. Stewart, B. A. Thompson, R. W. Tooley, A. D. Tuddenham, B. A. Tudgay, J. L. Turk, Maire P. Wallington, J. W. S. Webb, F. L. Whalley, Dorothy J. Whitney, J. R. Williams, A. G. Winfield, D. W. Wood, J. C. Worswick, A. P. J. Wynne-Jones, J. R. Young, K. J. Zilkha.

The following diplomas, and those mentioned in our issue of Jan 17 (p. 151), were conferred jointly with the Royal College of Surgeons.

D.A.—Ian Jackson.

D.I.H.—Dhundiraj Nilkanth Bhatavadekar, W. T. Buckle, P. N. B. Peacock, Dattatraya Ramadwar, E. S. O. Smith.

D.P.H.—T. C. R. Archer, E. M. Ensor, Syed Jawhar, G. S. Kambourian, Alan McGregor, Asoke Kumar Mitra, W. T. D. Ray, J. E. C. Robinson, J. P. Scrivener, F. J. Wickremasinghe, O. S. Williams.

Tributes to the late Philip Mitchiner

The Royal Medical Benevolent Fund has received £163 in donations made in tribute to the late Mr. Philip Mitchiner.

Royal College of Obstetricians and Gynæcologists

At a meeting of the council held on Jan. 31, with Mr. A. A. Gemmell, the president, in the chair, Leverhulme research scholarships for 1953 were awarded to D. C. A. Bevis, Ian Donald, and Ian Macdonald.

The following were elected to the membership:

D. M. Brodie, Patrick Bruce-Lockhart, D. S. Burris, K. G. Cockburn, S. B. Cooper, Janette G. Cowie, H. J. G. De Villiers, H. G. Dixon, Margaret M. Downes, E. M. Edwards, J. R. Elliott, A. H. Foate, G. S. Foster, A. E. Fyfe, G. H. Garfield, J. M. Gate, G. L. Gleeson, Louis Goldman, N. G. Gourlay, Michael Grant, R. W. Grayburn, J. M. Holmes, G. C. S. Hunter, Valentine M. Husband, Sarah I. Jacob, R. A. Kenihan, Kamala Khadenga, H. H. Kirk, B. V. Kyle, J. C. McCawley, John Macpherson, J. S. McVeigh, Jean Murray-Jones, T. J. Murphy Myles, L. M. Norburn, E. M. O'Dwyer, Selvam Panchalingam, R. M. M. Pratt, M. J. M. Solomons, W. K. Sutton, T. A. Thompson, R. S. Wurm.

Royal Society

Dr. F. M. R. Walshe, F.R.S., will deliver the Ferrier lecture of this society for 1953 on Dec. 10.

International Society of Orthopædic Surgery and Traumatology

This society is holding a congress at Berne from Aug. 30 to Sept. 3. The principle subjects chosen for discussion are Scoliosis and Surgery of the Hand. Further particulars may be had from the secretary-general of the society, Dr. J. Delchef, 34, rue Montoyer, Brussels.

Ergonomics Research Society

From Monday, April 13 to Thursday, April 16 at the Department of Human Anatomy, University of Oxford. this society is holding a symposium on Human Performance—Its Measurement and Limitations. Further particulars may be had from H. Murrell, Spinneys, Marlpit Lane, Headless Cross, near Redditch, Worcs.

Institute of Almoners

The annual general meeting of this institute will be held on Friday, March 13, at 6 P.M., at B.M.A. House, Tavistock Square, London, W.C.1, when Mr. L. Farrer-Brown, secretary of the Nuffield Foundation, will speak on Professionalism in the Health Service.

Society for the Study of Addiction

Prof. E. M. Jellinek, SC.D., consultant on alcoholism to the World Health Organisation, will give the fifth Kelynack lecture on Tuesday, Feb. 17, at 5 P.M., at Westminster Hospital Medical School, Horseferry Road, London, S.W.1. He will speak on International Aspects of Alcoholism.

British Association of Sport and Medicine

The first annual general meeting of this association will be held at Westminster Hospital Medical School, London, S.W.1, at 5 P.M., on Friday, Feb. 27, when Sir Adolphe Abrahams will speak on its aims and policy. Doctors interested in the medical aspects of sport will be welcome. Further information may be had from Dr. William Tegner, the hon. secretary of the association, c/o the British Olympic Association, 95, Mount Street, W.1.

Institute of Social Medicine

The address of this institute is now Social Medicine Unit. 8, South Parks Road, Oxford.

Horse Shoe Club

This organisation for promoting Anglo-American medical relations is anxious to compile a list of American doctors temporarily resident in this country. Names should be sent to Dr. C. S. Nicol, the hon. secretary, St. Bartholomew's Hospital, London, E.C.1.

Claiming Sickness Benefit

Owing to the influenza epidemic, doctors in some areas, particularly in the south of England, may not be able to see their patients without some delay. The Ministry of National Insurance reminds people claiming sickness benefit that they must notify the local National Insurance office of their illness within three days of its onset. But if a patient has not yet received a medical certificate he may send a note (written by himself or by a relative or friend) giving his name, address, National Insurance number, and the date on which the illness began. The formal claim on the doctor's "first medical certificate" should follow as soon as the doctor has been seen, and in any case within 10 days of the start of the illness.

D D D. THERAPY IN CUSHING'S SYNDROME

From the Pathology Department, University of Liverpool

D D D has the formula 2,2 bis-(parachlorophenyl)-1,1 dichloroethane, and is an insecticide related to D D T In 1948 and 1949 Nelson and Woodard reported the important discovery that, when dogs are given this substance by mouth in a dosage of about 20–50 mg per kg body-weight, the deeper layers of the adrenal cortex atrophy and disappear Within about a month, only the zona glomerulosa and a narrow outer part of the zona fasciculata remain Nichols and Gardner (1951) confirmed these findings and found that the dogs became relatively insulin-sensitive, though there was no disturbance of electrolyte balance Nichols and Sheehan (1952) described the development of the histological changes in the adrenal cortex, and studied the related disturbances of carbohydrate metabolism They found that such dogs could not be made diabetic with alloxan, but remained resistant to potassium intoxication

Such a striking and very specific destruction of the deep layers of the adrenal cortex raised the possibility that D D D might have considerable therapeutic value in patients whose symptoms indicate a hyperfunction of these layers—e g, adrenal virilism or Cushing's syndrome, and possibly some cases of diabetes or hypertension The difficulty was that dogs are the only laboratory animals known to develop the adrenal lesion as a result of treatment with D D D This substance had not previously been given to man, and thus there was no information as to whether it had any effect on the human adrenal The investigation to be described shows that, with the particular dosage used, D D D does not produce any significant clinical effect on Cushing's syndrome, and that at any rate it does not cause any permanent adrenal atrophy in this condition Nevertheless it is to be hoped that the investigation of chemically related substances will lead to the development of a method of reproducing in these patients the same degree of atrophy and reduction of function of the adrenal cortex as can be obtained in the dog

TABLE I—MEAN FIGURES OF GLUCOSE TOLERANCE AND INSULIN-TOLERANCE TESTS BEFORE D D D THERAPY

Test	Minutes				
	0	30	60	90	120
Glucose tolerance (mg per 100 ml)	83	161	172	149	102
Insulin tolerance (mg per 100 ml)	86	70	72	80	71

The patient treated in the present study was made fully aware of the experimental nature of the treatment, of the possible beneficial effects, and of the completely unknown risks We should like to record our thanks for her willing cooperation

INVESTIGATION

The patient married at the age of 20 She had no pregnancies, and menstruation continued regularly Her weight remained at its normal level of 109 lb, her height being 62½ inches Apart from a short attack of hepatitis when she was 23, her health was good until the onset of the endocrine disturbance At the age of 24 menstruation ceased and she gradually developed a classical and severe Cushing's syndrome during the next two yea She was admitted to hospital when she was 27, complaini of a rapid increase of weight, change in facial appearan lack of energy, occasional headaches, and sometim slight swelling of the feet

On examination she had the characteristic red "mo face," with moderate growth of hair along the side of the j and a little over the chin, considerable obesity, mainly of t trunk, purple striæ on the sides of the abdomen, and buffalo hump over the shoulders (see figure) Her weight w 154 lb There was mild acne of the face and trunk The pul hair was of masculine distribution The clitoris was r enlarged The uterus was small and the endometrium atroph Radiologically the skull appeared normal and there was decalcification of the spine or long bones, the left kidney h a double pelvis and ureters The blood pressure ranged betwe 200/135 and 185/120 mm Hg The electrocardiogram w normal, apart from a negative T_3

Several blood counts gave mean figures as follows 107%, red cells 5,500,000 per c cm, and white cells 98 per c mm Kepler tests showed good diuresis, with a uri output in the 2nd hour more than double the volume of t night urine, the Kepler index ranged from 56 to 116 Th basal metabolic rate (B M R) was −16% and −21% Ther was a moderate increase of nitrogen excretion in the urin and the urinary excretion of 17-ketosteroids and 11 oxycort coids was above normal (These and other biochemic findings are shown in table III) The patient was relativel resistant to insulin The mean figures of two glucose toleranc tests after a dose of 50 g of glucose by mouth, and of thre insulin-tolerance tests after an intravenous injection o 7 5 units of insulin, are shown in table I

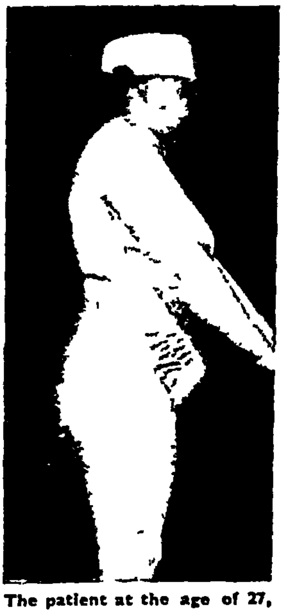
TABLE II—MEAN FIGURES OF GLUCOSE TOLERANCE AN INSULIN TOLERANCE TESTS AFTER COMPLETION OF SECO COURSE OF D D D

Test	Minutes				
	0	30	60	90	12
Glucose tolerance (mg per 100 ml)	117	200	202	184	12
Insulin-tolerance (mg per 100 ml)	175	122	160	160	15

Treatment

The patient was studied for an observation period o 12 weeks before the administration of D D D was begun Her weight gradually increased to 168 lb

The first course of treatment with D D D lasted 18 days The dosage was 1 06 g daily, equal to 13 3 mg per kg body-weight, the total amoun given in this course was 19 g administered by mouth as 10% solution in oil of arachis There was no recognisable clinical effect The blood-pressure continued in the range of 210/120 to 190/110, and the weight increased to 176 lb The only biochemical change was a fall in the serum-sodium level Glucose-tolerance tests and insulin tolerance tests gave curves substantially the same as before treatment



The patient at the age of 27, showing the striæ on flanks and abdomen

An observation period of 39 days followed, in case delayed effects of D D D might appear No such effects were seen The blood-pressure ranged from 200/120 to 180/120 The patient was next given a second course of treatment, which lasted for 30 days The dosage was 2 84 g daily, equal to 34 6 mg per kg, the total amount in this course was 85 g The drug was again given dissolved in oil of arachis No clinical effects were observed, apart from the fact that the blood-pressure was

BODY-FLUID DEPLETION*

D. A. K. BLACK
M.D., B.Sc. St. And., F.R.C.P.
TURER IN MEDICINE IN THE UNIVERSITY OF MANCHESTER

VHEN physicists ascend from Natural to Metaphysical losophy, they show us a world whose apparent solidity nerely the paradoxical expression of a changing flux mponderable particles. Process likewise masquerades structure in biology and medicine, and nowhere more than in the fabric of body-fluid. Our notions of mical equilibrium within and between the different ases of body-fluid are being displaced by concepts ed on a "steady state," which requires the expense of rgy to maintain its precarious stability. Bertalanffy 50) has summarised the characters of steady states, nting out that in open systems such as living organisms increase of entropy—which men call death—is oided only by the continued import of energy-rich stances. In this way, the organism can locally and nsiently defy the second law of thermodynamics, intaining a bubble of organisation in an environment increasing disorder.

The relevance of a dynamic approach to the study of dy-fluid becomes apparent when we consider either e very different composition of fluid within and outside e cells, or the rapidity with which changes induced in e phase of body-fluid evoke responses in other phases. milarly, methods of study have evolved from the timation of plasma composition through the classical lance techniques to the present time, in which the timation of volumes of distribution of chemically or ysically labelled markers gives us the means of sessing rapid changes in body-fluid distribution. In is first lecture I shall discuss some general aspects of ody-fluid in relation to the treatment of clinical fluid epletion; in the second lecture I shall deal more ecifically with experimental and clinical depletion of otassium, the predominant cation of intracellular fluid.

Total Body-water

Changes in the water content of the body can be stimated from the body-weight and fluid balance; but he total amount of water in the living body at any time an only be assessed by dilution methods. In principle, a measured amount is given of a substance which quickly diffuses through the whole of body-water; when equilibrium has been reached, the concentration of this substance in plasma water is determined, and the total volume of distribution of the substance can then be calculated. In practice, corrections have to be made for nequalities of distribution, and for excretion of the test substances during the interval between administration and the attainment of equilibrium. Urea, thiourea, antipyrine, and deuterium have all been used for this purpose. The antipyrine method (Soberman et al. 1949) agrees fairly well with estimations based on deuterium given as "heavy water." The most extensive studies with deuterium come from F. D. Moore's team at Boston (Edelman et al. 1952). They show clearly that the water content of the body decreases as age advances, and that in the same age-group men have a higher water content than women, as a percentage of total body-weight. This sex difference is probably largely a matter of the different fat content of the two sexes, for the "lean body mass" is surprisingly constant in composition (McCance and Widdowson 1951). In Moore's series, the percentage of water in the bodies of 34 young men (ages 17–34) ranged from 53·3 to 70·3, with a mean of 61·1%; the mean body-water in 18 young women was 51·2%. Dilution methods, even with deuterium, depend on equilibrium of the test substance with body-fluid; so in accepting their results we owe much to their general agreement with the results of an analytical tour-de-force carried out by Widdowson, McCance, and Spray (1951). By chemical analysis of the cadaver, they found 61·8% water in a man of 25, and 56% water in a woman of 45.

Physical State of Body-fluid

When we cut across normal tissue from which the blood has been allowed to drain, no fluid escapes, although the tissue looks moist, and we know it contains more than half its weight of water. We are obviously dealing with something which resembles a jelly rather than a water-filled sponge. Protoplasm has long been known to be a gel; and the recent intensive study of the extracellular supporting tissues, reviewed in the Goulstonian lectures last year (Kellgren 1952), has shown us that they, too, are probably in the gel form. The firmness of the gel depends largely on the degree of polymerisation of glycoprotein, and in rapidly growing tumours or in the symphysis pubis of pregnant guineapigs the "ground substance" is much more fluid (Gersh 1949–50). A simple increase in the extracellular tissue fluid, as in œdema, is also associated with the appearance of watery fluid, but the transformation from gel to sol may be incomplete, as suggested by the variable success of Southey's tubes in withdrawing œdema, and the different "feel" of œdematous tissues from case to case. Small molecules and ions diffuse rapidly through gels, but larger molecules such as inulin may be impeded; an inulin infusion takes five hours to attain equilibrium with extracellular fluid (Schwartz et al. 1949), whereas hypertonic salt has diffused through the extracellular space within twenty minutes (Black, Platt, and Stanbury 1950). Even if, as seems likely, body-fluid is in fact a solid of high water content, we can continue to use this, the accepted term, in a Pickwickian sense.

Distribution of Body-fluid

The basic division of body-fluid is effected by the aggregate of cell walls. Extracellular and intracellular fluid differ radically in their ionic composition; by comparison, plasma is strikingly similar in composition to extravascular extracellular fluid, which for brevity's sake we may call interstitial fluid. As a first approximation, it may be said that the partition of body-fluid into extracellular and cellular fluid depends on the relative amounts of sodium and potassium in the body; while the partition of extracellular fluid into plasma and interstitial fluid depends on the total mass of plasma-protein, whose osmotic attraction counterbalances the hydrostatic forces tending to expel fluid from the capillaries. The total extracellular fluid can be measured by the volume of distribution of inulin after equilibrium has been attained by long-continued infusion; Schwartz et al. (1949) in seven normal men found values ranging from 14 to 18% of body-weight, with a mean of 16·2%. Cell fluid can be measured only by the difference of estimates of extracellular fluid and total body-fluid; comparison of inulin and deuterium results gives a mean figure of 45% of body-weight. In infants, a much higher proportion of body-fluid is extracellular (Widdowson and Spray 1951).

Sodium forms more than 90% of the base of extracellular fluid (E.C.F.) and the osmotic pressure of E.C.F. depends almost entirely on its electrolyte content. Claude Bernard's vision of an osmotically stable internal environment thus implies a close relation between E.C.F. volume and E.C.F. total sodium. In his Goulstonian lectures, McCance (1936a) described experimental work on man which showed both the validity and the limitations of

---

* The first Goulstonian lecture for 1953, delivered before the Royal College of Physicians on Jan. 13. The second lecture will appear in a forthcoming issue.

In our opinion the true values are very close to the figures given, though they might be a little lower Assuming the maximum errors both in the estimations and the correction, the true values cannot possibly be less than half the figures given "

DISCUSSION

This experimental therapy was undoubtedly a complete failure from the clinical aspect The biochemical findings during the second course of D D D treatment raised the slight possibility that there might at that stage have been some increased adrenal production of deoxycorticoid-like substances and a decreased production of androgens Histologically there was, however, no evidence that the adrenal cortex had been affected in any way by the treatment.

The problem arises of why, in man, D D D does not produce atrophy and loss of function of the deeper zones of the adrenal cortex

In the dog D D D certainly accumulates in the adrenal cortex as well as in the adipose tissue It is not known whether D D D produces its effect on the dog's adrenal by direct toxic action in the gland or whether it blocks the action (or the production) of corticotrophic hormone Nevertheless it is clearly important to know whether D D D is accumulated in the adrenal gland and adipose tissue of man in the same way as it is in the dog

Before the onset of her illness the patient weighed 50 kg and was of normal nutrition, she would have a normal amount (say about 5 kg) of adipose tissue distributed in her body If it is assumed that her subsequent increase of weight was nearly all due to fat, she presumably had about 45 kg of adipose tissue when the specimens of tissue were obtained for analysis Thus it may be calculated that there was a total of 16 g of D D D in the adipose tissue of the body at the time of the first biopsy (7 weeks after she had taken 104 g), and 6 g at the time of the second biopsy (11 weeks after receiving a further 23 g)

To compare the results of animal experiments with the present case, the figures may be considered in terms of the amount of D D D per 100 g of fat Finnegan et al (1949) gave D D D orally to dogs in a dosage of 25 mg per kg for four weeks Immediately at the end of this period the dogs had 30–88 mg of D D D per 100 g of fat If the dosage had been 35 mg per kg, it may be inferred that the dogs would have had 40–120 mg of D D D per 100 g of fat at that time These workers have shown that D D D is slowly broken down, some of the metabolic products may remain for a time in the fat, but others are excreted in the fæces and urine Thus, after the administration of the drug is discontinued, there is a progressive and gradual reduction in the amount of D D D in the fat

The present patient was given 35 mg of D D D per kg for 4 weeks The immediate concentration in the fat is not known, but after an interval of 7 weeks there still remained 35 mg of D D D per 100 g of fat During the last course of treatment she was given about a quarter of the amount given in the second course After a further interval of 11 weeks, there was 14 mg of D D D per 100 g of fat These findings suggest that in man the initial accumulation of D D D in the fat had probably been roughly about the same as in the dog, and that the lower figures when the biopsy specimens were taken resulted from the gradual metabolism of the D D D in the fat

Finnegan et al found that the adrenals of the dog contained 0–21 mg of D D D per 100 g of tissue when the fat contained 30–88 mg of D D D per 100 g In the present patient the amount of D D D per 100 g of adrenal tissue was about a third of that per 100 g of fat There is therefore nothing to indicate any important difference between the rate of accumulation of D D D in the adrenal of man and the dog

The absence of any significant effect on the adren of the present patient is thus not apparently related any failure to accumulate D D D in the adrenal gland It must be considered as due to some lack of sensitivi of the human adrenal to D D D, the precise cause this remains to be ascertained

It is of interest that the toxic symptoms occurre when the D D D was given in olive oil, but not when was given in oil of arachis Possibly there may hav been some interaction with the oil, or some difference the rate of absorption This needs to be considered further work on the subject

SUMMARY

D D D is a substance which, when given experimentall to dogs, produces severe atrophy and loss of function the deeper layers of the adrenal cortex

An attempt was made to reproduce this adrenal atroph for therapeutic purposes in a patient with Cushing' syndrome She was given a total dosage of 127 g D D D in three courses of treatment

No recognisable clinical, biochemical, or histologic response was obtained

Biopsies of fat and of adrenal gland showed that D D was taken up by these tissues in the human patient amounts comparable to those in the dog The insensitivit of the human adrenal gland to D D D thus does no appear to be due to any failure of the substance accumulate there

ISONIAZID-RESISTANT STRAINS OF TUBERCLE BACILLI

THEIR DEVELOPMENT AND STABILITY

Margaret Barnett
B H Sc N Z

S R M Bushby
M Sc Brist, Ph D Lond

OF THE WELLCOME RESEARCH LABORATORIES, BECKENHAM KENT

D A Mitchison*
M B Camb

LECTURER IN BACTERIOLOGY, POSTGRADUATE MEDICAL SCHOOL OF LONDON

Strains of *Mycobacterium tuberculosis* resistant to isonicotinic acid hydrazide (isoniazid) have been produced in vitro (Steenken et al 1952, Buck and Schnitze 1952, Pansy et al 1952, Middlebrook 1952, Hobby and Lenert 1952, Rist et al 1952, Goulding et al 1952), and they occur frequently in the sputa of patients treated with the drug (Medical Research Council 1952)

During experiments in which resistant strains were produced in vitro, we found that in certain circumstances these strains were unstable both in viability and in their degree of resistance An investigation of the stability of resistant strains from patients also indicated that some of these tended to become less resistant during subculture without isoniazid, and probably to be then sufficiently sensitive to respond to therapeutic concentrations of the drug Chemotherapeutic studies in mice and guineapigs were therefore made with two of these unstable strains and a variant of H37Rv having a similar degree of resistance low-potassium diet the body is capable of conserving potassium to a greater extent than has often been supposed (Fourman 1952); but potassium conservation sets in more slowly than that of sodium (Black and Milne 1952), although in the end the urine may contain potassium in lower concentration than the plasma.

---

* In receipt of a grant from the Medical Research Council

Even this brief summary of body-fluid regulation must have brought out the central rôle of the kidneys, whose task it is to protect us from our dietary variations, privations, and indiscretions. In his Lumleian lectures last year, my chief, Prof. Robert Platt, was able to show how well the chronically diseased kidney can adapt itself to its straitened circumstances, and put up a good performance of homœostasis even when its excretory function is largely spent (Platt 1952). Unfortunately, even the normal kidneys can only continue their efficient regulation of body-fluid if the circulation through them is adequate, and if water is freely available for urine formation. Severe depletion of body-fluid withdraws the very conditions under which the kidneys function efficiently, and is to that extent self-perpetuating.

Body-fluid Depletion

In his Croonian lectures of 1946, Marriott performed a great service to medicine and surgery in elaborating the clinical distinction between water and salt depletion. My own preference is to speak of "sodium" rather than of "salt" depletion, in order to emphasise the importance of sodium in maintaining E.C.F. volume, and also to remind ourselves that the electrolyte lost in this condition is not sodium chloride but a mixture of chloride, bicarbonate, and other anions in varying proportions, depending on the particular channel of fluid loss. Although the term "salt depletion" is entirely adequate to express the important distinction which Marriott had in mind, it also suggests that salt solution, or "saline," is the correct replacement solution for E.C.F. depletion. Saline is certainly preferable to glucose solution in sodium depletion, but when large amounts of sodium have to be given —and I hope to show you later that this is often necessary —the use of saline will provoke acidosis, and a proportion of the sodium should be given in the form of bicarbonate or lactate. Van Slyke (1948) points out that "physiological" 0·9% saline is really unphysiological, as a substitute for E.C.F.

I have little to say of primary water depletion, except to emphasise the generalisation, implicit in Marriott's account, that water depletion arises from defective intake of fluid, whereas sodium depletion is mainly caused by abnormal losses of fluid. This generalisation really stems from the inevitability of water loss in sweat, urine, and expired air, in contrast to the effective conservation of sodium under all ordinary conditions. Like most clinical generalisations, it needs its proper glosses: as that in fever enhanced water loss may speed the depletion of water; and anorexia may aggravate the effects of sodium loss by enhancing the negative balance of sodium. But I think it holds true in respect of root causes.

My concern in the rest of these lectures will be with deficiencies of body-fluid which arise not from any lack of access to water—often indeed in spite of a free water intake, because of the compelling force of electrolyte depletion. Sodium depletion leads to shrinkage of the extracellular phase of body-fluid, and potassium depletion to shrinkage of the intracellular phase. Either deficiency may be complicated by change in the acid-base balance, and may even predispose to such change; but I shall discuss this as an incidental matter, even though in a few clinical contexts it may overshadow the change in total electrolyte. *Vitae summa brevis spem nos vetat inchoare longam*; and on this occasion life's own injunction to brevity is reinforced by the need to fit a large subject into little room.

Causes of Sodium Depletion

Dietary deficiency of sodium is not in itself a sufficient cause of serious sodium depletion, though it may aggravate depletion produced in other ways. Cation exchange resins are likewise ineffective in producing sodium depletion, for they do little more than prevent the absorption of dietary sodium; when cation exchange resin is added to a sodium-free diet, the excretion of sodium in the stools is not significantly increased (Mateer et al. 1951). Clinically significant sodium depletion arises only when loss of sodium from the body is abnormally great. In the tropics, and in mines and stoke-holds, the necessities of thermoregulation impose a loss of sodium in the sweat which may suffice to bring about either acute or chronic sodium depletion in otherwise fit people. In disease, sodium depletion arises either from external loss of gastro-intestinal secretions, or from increased urinary excretion of sodium. The various gastro-intestinal secretions contain about 1000 m.eq. of sodium per day, which represents about a third of the total sodium content of the body, and is five times as great as the average dietary intake of sodium. The stools normally contain less than 10 m.eq. of sodium per day; reabsorption of alimentary-tract sodium is carried out with an efficiency comparable to that of the renal tubule. Whenever appreciable amounts of gastro-intestinal secretions are lost to the body, the risk of sodium depletion arises; such losses may come from vomiting or diarrhœa, from fistulæ, or from continuous aspiration. No-one who has seen patients with cholera can doubt the effectiveness of this mechanism of sodium depletion, which can lead to circulatory collapse within a few hours; but fortunately the wastage of digestive juices is usually less extreme, and the syndrome of sodium depletion manifests itself more slowly. While gastro-intestinal disease is by far the commonest cause of clinical sodium depletion, urinary losses of sodium are not rare, and the channel of sodium loss is far less obvious than in the gastro-intestinal group. This occult quality of urinary sodium loss gives it diagnostic interest out of proportion to its absolute frequency.

Primary renal disease seldom leads to excessive sodium excretion. In most cases of renal failure, the decrease in glomerular filtration, and so in the amount of sodium presented to the tubules, is compensated by decreased sodium reabsorption (Platt 1950); the serum-sodium remains within normal limits until lowered by terminal vomiting or diarrhœa. Rare cases have been described in which renal disease has been associated with excessive sodium excretion—the "salt-losing nephritis" of Thorn et al. (1944). These may be distinguished from Addison's disease by their lack of response to deoxycortone. Apart from intrinsic renal disease, sodium may be lost to excess in the urine in Addison's disease, in osmotic diuresis, and in metabolic acidosis. Pitts (1952) presents a masterly discussion of the mechanisms by which adrenal deficiency enhances sodium excretion. In osmotic diuresis, the "loading solute," which may be either native (glucose) or foreign (mannitol) to the body, is excreted in large amount, and imposes a constraint on reabsorption by its osmotic activity; the urine volume rises, and also the rate of sodium excretion, though the concentration of sodium is diminished, unless sodium be itself one of the loading solutes, as in sodium sulphate diuresis. Clinically, osmotic diuresis contributes to sodium depletion in diabetic coma, with glucose as the loading solute (Brodsky et al. 1950). Urea may act as a loading solute in chronic renal failure (Platt 1951), and also in the water-and-salt diuresis which characterises the "early diuretic phase" of recovery from acute tubular necrosis (Bull et al. 1950). When excessive amounts of anions are produced in the body from any cause, such as increased breakdown of fat or protein, their excretion must be partly covered by base; initially this is largely sodium, but normally the

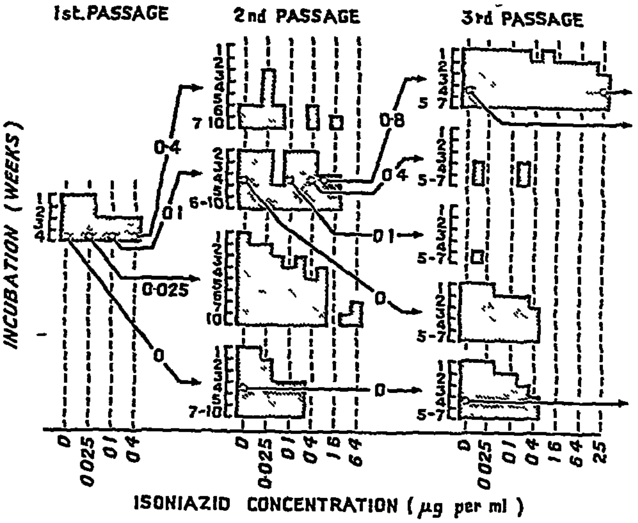

Fig 2—Results of first three passages of variant B in liquid medium

Shading indicates growth The sensitivity test on the left was inoculated with H37RV, arrows link the bottles containing the inoculum to the sensitivity tests set up from them and pass through numbers indicating the isoniazid concentration in the inoculum bottle The vertical interrupted lines are drawn at intervals of every two concentrations

cultures had poor viability Similar poor viability occurred with strain A (passage 4, fig 1), and the same tendency has also been observed in another series of resistant variants of H37RV

A further series of four passages, in each case passaging from the bottle with the highest tolerated concentration and from the bottle without isoniazid, showed (1) that it did not appear possible to obtain a resistant strain growing in more than 25–50 µg of isoniazid per ml, (2) that, apart from reversion after a single passage in isoniazid, resistant strains subcultured once without isoniazid did not lose their resistance, and (3) that the viability of the strain appeared normal after the third subculture

The variant B was finally subcultured eight times without isoniazid without any loss of resistance

Resistant Strains from Solid Medium

Serial twofold dilutions of isoniazid were made in Herrold's medium and Dubos oleic acid-albumin agar medium as described previously (Mitchison 1952) and the slopes were inoculated with 0 02 ml of a Dubos culture of H37RV and Pr, a strain recently isolated from a patient not previously treated with any chemotherapeutic agent The degree of growth after 6 weeks' incubation is shown in table I From the tubes indicated, colonies were picked off into Dubos medium without isoniazid, and after 18 days' incubation were tested for sensitivity Among the variants originating from concentrations which had largely inhibited growth, three out of nine failed to grow in the first subculture, and, of those that grew, one appeared to be of poor viability in the sensitivity test Only one of the subcultures (Pr from Dubos medium containing 1 6 µg of isoniazid per ml) definitely proved to be resistant, but one other (H37RV from Dubos medium containing 0 4 µg per ml) grew in a higher concentration after 28 days' incubation than would be expected with a normally sensitive strain

Summary

These experiments with resistant variants induced in vitro seem to show that (1) the variants rapidly revert to their original sensitivity after having been in contact with isoniazid for one subculture but do not revert after longer periods of contact, and (2) when first produced they tend to die more rapidly than do sensitiv strains

STABILITY OF RESISTANT STRAINS FROM PATIENTS

Twenty strains from patients were obtained by treating sputum with 4% sodium hydroxide and culturing on Löwenstein Jensen medium Sensitivity tests on solid medium were made on the resulting cultures From the control tube of the test, two successive subcultures were made in Dubos medium, and from the second of these, after 10 days' incubation, a further sensitivity test was made Thus the two sets of sensitivity tests were separated by three subcultures in medium without isoniazid

The results are shown in table II Of sixteen resistant strains six showed no loss of resistance, whereas ten showed a considerable loss In only one strain, however, was the final sensitivity equal to that of a fully sensitive strain, suggesting that strains with a low degree of resistance are more stable

RESULTS OF IN-VIVO EXPERIMENTS

Experiment 1

The resistance in vivo of the H37RV variant A1 was measured in mice and guineapigs To obtain a sufficient number of organisms for the test, a flask of Dubos medium containing 1 µg of isoniazid per ml was inoculated from the tube of the first passage containing the highest tolerated concentration of isoniazid

The instability following the first passage that had been demonstrated in vitro was also measured at the same time in vivo by infecting animals with the variant after a single passage in medium without isoniazid (variant A0) For this purpose a second flask of medium without isoniazid, was inoculated with the same

example, McCance (1936b) describes one subject who lost 17·5 g. of sodium during depletion, but retained 21 g. during recovery; there was a gain in weight equal to the gain in extracellular fluid volume which would correspond to the observed increase in sodium content of the body at the end of the experiment. Again, Atchley et al. (1933) give figures showing discrepancy between loss of sodium and subsequent gain in diabetics allowed to enter acidosis and then recover.

Neither of these rather direct methods can give a practical clinical assessment of sodium depletion, for the data required for a prospective assessment are lost in the past, while the retrospective assessment would be available only when the depletion had been corrected. We are left with indirect methods, which include isotope dilution, the estimation of the serum-sodium level, and the more purely clinical assessment of dehydration and sodium loss. With isotope dilution methods, it is possible to make a fairly accurate assessment of the exchangeable sodium content of the body; but to convert this to an assessment of the depletion, it is necessary to compare this with a normal value, and here we encounter the wide range of normal variation. Nevertheless, observations on the exchangeable sodium content in clinical dehydration, supplemented by observations on the same patient after recovery, would form a useful addition to our quantitative knowledge of clinical sodium depletion. Without this background of information, the isotope method is of no present value in the clinical assessment of sodium depletion; but in five years our hunger for numerical precision may make it seem indispensable.

The clinical assessment of sodium depletion is an exercise in which no merit attaches to dissociating the evidence derived from history, examination, and chemical analysis. None of these, and perhaps least of all the chemical analysis, gives us by itself all the information which we require for considered treatment. The history should establish the channel of sodium loss, and give us at least an indication of its amount. In the great majority of these patients, sodium has been lost from the alimentary tract in an obvious way; renal loss of sodium is infrequent by comparison, and diabetes or Addison's disease have usually been recognised before the onset of dehydration. Physical examination shows the presence of dehydration and of peripheral circulatory failure; and in conjunction with the history allows some estimate of the amount of sodium depletion. By the time dehydration is just detectable clinically, there must already be a considerable sodium deficit; this may be of the order of 200 m.eq., corresponding to 1·5 litres of extracellular fluid, for Atchley et al. (1933) found such a sodium deficit in diabetics who were allowed to become acidotic but were not notably dehydrated. In acute sodium depletion with definite dehydration, as in diabetic coma, the sodium deficit is probably around 400–500 m.eq.; at any rate, Nabarro et al. (1952a) found that the retention of sodium in such patients during recovery ranged from 273 to 571 m.eq., with a mean of 455 m.eq. Much larger amounts of sodium may be lost in chronic dehydration, the result of long-continued loss of gastro-intestinal fluids. I have lately seen a patient who had been losing bile and pancreatic secretion for some weeks from a duodenal fistula. He was severely dehydrated, with cord-like veins and eyes staring from lid retraction; the serum-sodium was 118 m.eq. per litre. He was given no less than 1400 m.eq. of sodium in one protracted infusion. He was much better, with full veins and no appearance of exophthalmos, but his serum-sodium was still below normal, and his deficit had presumably not been fully corrected.

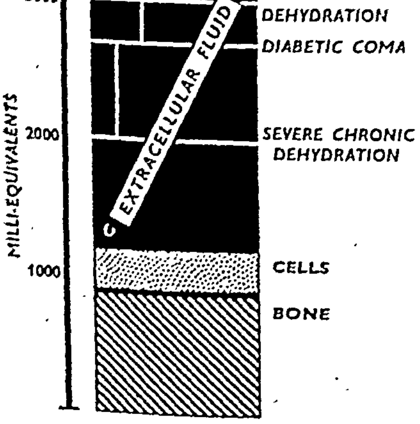

Fig. 1—Order of magnitude of different sodium deficits in relation to the normal distribution of sodium.

Given historical evidence of sodium loss, and clinical evidence of dehydration, we can get further help from chemical analysis of the blood in assessing the amount of the sodium deficit. It may be very difficult to get blood from a superficial vein, and on one or two occasions I have had to withdraw blood from the femoral vein. With a flame photometer, sodium and potassium concentrations can be estimated on 1 ml. of serum; but whenever possible the chloride and bicarbonate should also be estimated, the whole sample being taken under liquid paraffin. A raised blood-urea, hæmatocrit, or plasma-protein level is often found in dehydrated patients, but in guiding treatment they are less important than knowledge of the electrolyte concentrations.

Treatment of Severe Sodium Depletion

No special difficulty arises in the treatment of acute sodium depletion, where the sodium deficit is of the order of 500 m.eq., an amount which can be restored by giving 3 litres or so of "normal" saline. If the first litre of normal saline is given quite rapidly, say in an hour, the circulation to the kidneys is sufficiently restored in moderate sodium depletion to enable them to act selectively, excreting a higher proportion of the chloride than of the sodium. We may observe in passing that such is the normal kidney's daily task—to conserve bicarbonate in the body-fluids although our sodium intake in the diet is almost wholly in combination with chloride. It is generally accepted that amounts of sodium chloride of this order can be given without producing significant acidosis (Peters and Van Slyke 1931). When sodium depletion is already complicated by metabolic acidosis, as in diabetic coma, it is better to give one litre in three of the replacement fluid as *M*/6 sodium lactate instead of as *M*/6 sodium chloride, or "normal saline."

Chronic severe sodium depletion presents a more difficult problem in several ways—the large amount of sodium needed, the acidifying effect of really large sodium chloride infusions, the frequent co-existence of potassium depletion which may be intensified by massive sodium infusion. I shall devote the rest of this lecture to the management of this type of sodium depletion, which is almost always associated with severe and prolonged loss of gastric, pancreatic, or intestinal secretion. This is a syndrome where proper treatment should bring physician and surgeon together. The physician can often restore electrolyte balance, but is powerless to arrest the continuing fluid loss; on the other hand, the surgeon, unless he be very exceptional, may make more mistakes than the physician in trying to make this type of patient "safe for surgery."

Before advocating special measures of treatment for these patients with severe sodium deficiency, I must first try to establish that their sodium deficit is in fact 1000 m.eq. and upwards—half or more of the normal extracellular sodium content of the body. The channel of sodium loss is certainly adequate to account for deficits of this magnitude; with the exception of gastric juice, the various alimentary secretions are equivalent in sodium content to extracellular fluid, and losses of 8–9 litres of spleen of one animal infected with M2, there was no evidence of infection in the treated animals Tuberculosis was widespread in the untreated animals

DISCUSSION

In a rather ambiguous statement Steenken and Wolinsky (1952) implied that attempts to induce resistance by serial subculture in increasing concentrations of isoniazid at 14 day intervals produced little or no increase in resistance A longer period of incubation, 26–57 days in our experiments, allowed a definite and more rapid development of resistance During this period growth occurred in progressively higher concentrations of isoniazid Goulding et al (1952) and Mitchison (1952) have described the destruction of isoniazid in Dubos medium at 37°C, and it might be thought that persisting sensitive organisms were growing because the isoniazid was destroyed However, the resistance of the strains during the next passage was increased, though not always to the extent that might be expected from the isoniazid concentration originally in the inoculum bottle It thus seems likely that a combination of selection of resistant bacilli and destruction of isoniazid is responsible for the shift in the inhibitory end point found during prolonged incubation, as suggested by Goulding et al (1952)

The previous reports on the stability of artificially produced isoniazid-resistant strains have been rather confusing Pansy et al (1952) reported that variants of B C G grown once in the presence of isoniazid tended rapidly to revert to sensitivity This was also found by Szybalski and Bryson (1952) using *Myco ranæ*, and they suggested that it might have been because the resistant variant had been rapidly overgrown by faster-growing sensitive organisms Knox et al (1952) and Fisher (1952) stated that resistant variants of H37RV derived by multiple passage in the presence of isoniazid (similar to our variant B) were stable on subculture without isoniazid These reports are therefore in agreement with the behaviour of our two resistant variants A and B which were unstable only after the first passage in the presence of isoniazid The initial instability was also confirmed by the in-vivo tests, since mice infected with variant A1 were only partially protected by isoniazid, whereas mice infected with variant A0 were completely protected

Three possible mechanisms for the initial instability can be suggested

(1) When an inoculum from the growth in medium containing isoniazid was transferred to medium without isoniazid a few sensitive organisms surviving the bacteriostatic concentration were also transferred These might grow more rapidly and take the place of the resistant ones in the isoniazid free medium This explanation is unlikely since, even if the resistant strain did not multiply at all, a sufficient number of resistant bacilli would be transferred from the isoniazid free medium to initiate growth in the subsequent sensitivity test

(2) The resistant organisms may have had poor viability, and most or all of them may have been dead when transferred to isoniazid free medium Sensitive organisms, present either as survivors or (less likely) as black mutants from the resistant population might then have multiplied and taken their place This seems probable, since with both variants A and B it was shown that some of the resistant cultures appeared to be poorly viable after the first two or three subcultures in the presence of isoniazid Fisher (1952) has shown that a strain similar to B differs in its growth requirements from H37RV since it did not grow in a purely synthetic medium Further, some subcultures from colonies on solid medium containing isoniazid failed to grow on subculture, a finding also reported by Karlson and Ikemi (1952a)

(3) The process of development of resistance may not involve selection of mutants but may depend on the formation of an adaptive enzyme system not genetically determined This system, though at first unstable, might acquire stability during growth in the presence of isoniazid and be transmitted to subsequent generations This explanation involves acceptance of the theory of inheritance of acquired characteristics and appears unduly complicated

Similar mechanisms may be involved in the tendency of resistant strains from patients to lose part of their resistance It should be noted that our strains were subcultured entirely without isoniazid, hence it would be likely that they contained a proportion of more sensitive organisms which had survived the effect of the isoniazid present in the body It is therefore more probable that these sensitive

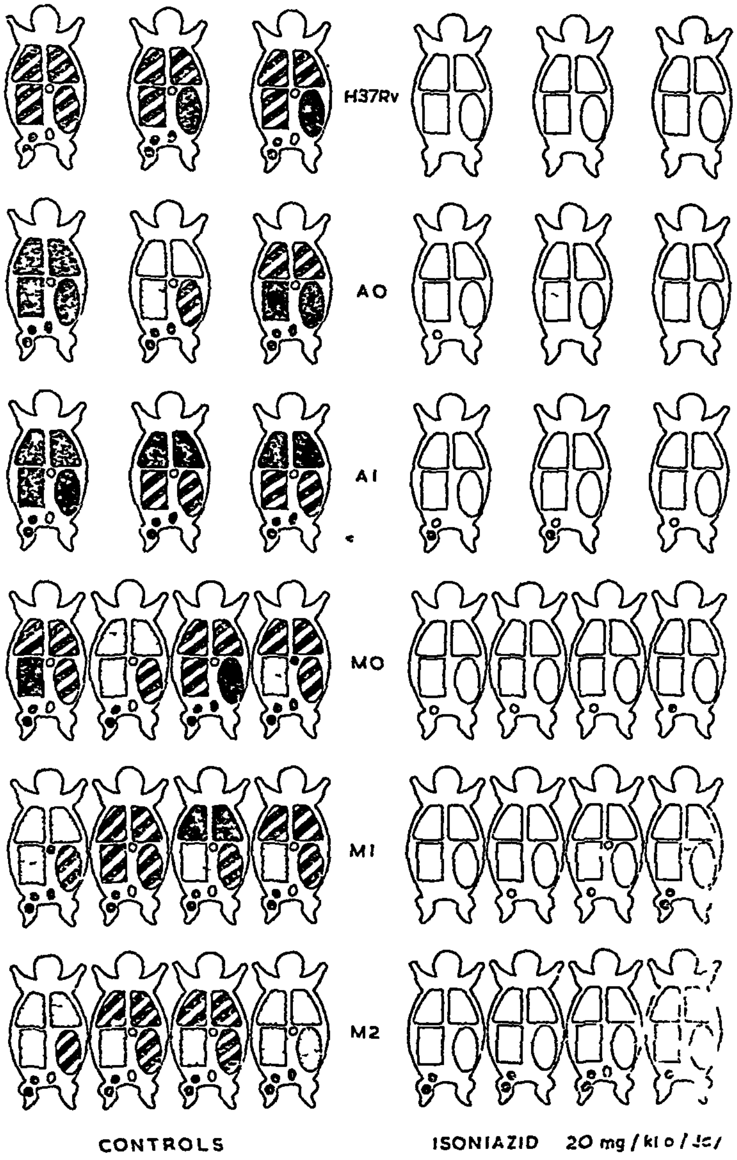

Fig 3—Chemotherapeutic experiments in guineapigs

The extent of tuberculosis in the organs is indicated by the degree of shading complete shading indicating maximal involvement, and stippling minimal involvement The liver is indicated by a rectangle, and the spleen by an oval From the right leg upwards are indicated the site of inoculation, the draining inguinal glands, the sublumbar gland, and the cœliac gland Enlarged glands are marked by open circles, which are shaded if the glands were caseous loss of gastric fluid, and of intestinal fluid respectively; these can be kept in readiness, and this avoids the delays inherent in a perpetual ad-hoc approach. The maintenance requirements of patients who cannot take food and water by mouth have been reviewed in some detail by Gamble (1951); he recommends 2 litres of 5% glucose daily to cover water losses, and to exploit the protein-sparing effect of carbohydrate. In patients who can eat and drink, thirst is the best guide to their maintenance water requirement.

These severely dehydrated patients whom we are discussing often have a sodium deficit equivalent to 10 litres or more of normal saline. When we add to this the replacement of current loss and the maintenance of water intake, it will be seen that the fluid requirement may be very high, the volume to be infused amounting to perhaps 12 litres of normal saline and 2 litres of glucose. I have suggested elsewhere (Black 1951) one expedient whereby the intravenous traffic can be kept down to a reasonable level—we may be content to allow several days for the correction of the existing deficit. Further experience has convinced me that this method may suffice for patients with moderate dehydration, but that severely dehydrated patients need more vigorous treatment, and it is specially important to restore the renal circulation as soon as possible. The large amounts of salt needed cannot be given by mouth in time, and similarly subcutaneous saline with hyaluronidase would not seem to offer sufficiently rapid replacement, in adults at least. Large amounts of hypertonic saline can be given to normal people without obvious harm; and I have also given considerable amounts of hypertonic saline to patients with anuria, who often have a low serum-sodium, and in whom it is desirable to keep fluid intake low. I believe there is a place for hypertonic saline infusion in patients with a large and definitely established sodium deficit, a low serum-sodium, and no condition which interferes with oral water intake. Such patients are not common, but I have treated 4 in the past year with 5% saline and molar lactate in amounts ranging from 500 ml. to 2 litres. In all of them the clinical improvement was definite, and there were no untoward effects. In 3 of them, I have observations comparing the amount of water actually drunk with that required to dilute the hypertonic sodium solutions down to isotonicity. Table I shows that the positive water balance, even neglecting insensible losses, was considerably less than the water needed to dilute down the hypertonic infusion; this would indicate that under such circumstances substantial amounts of water are available from the cells. In patient 3, infusion of the same amount of sodium as normal saline would have meant loading the patient with several litres of extra water, and his intracellular plethora would not have been so promptly relieved. Although the indications which I have given for hypertonic saline are limited, the results in suitable patients can be dramatic.

TABLE I—APPARENT "WATER FROM CELLS" IN PATIENTS GIVEN HYPERTONIC SALINE

Patient	Volume of hypertonic infusion (ml.)	Theoretical "water of dilution" (ml.)	Excess of water drunk (ml.)	"Water from cells" (ml.)
1	350	1400	600	800
2	1600	6400	5000	1400
3	2000	8000	2800	5200

When these large amounts of sodium have to be given, whether in isotonic or hypertonic solution, attention must be given to acid-base regulation and to potassium depletion. Large amounts of sodium chloride infusion lead to lowering of the plasma-bicarbonate, and this "dilution acidosis" (Shires and Holman 1948) may be clinically important when the renal defence of extracellular fluid pH is impaired. When there is no pre-existing acidosis or alkalosis, a fifth of the sodium in large infusions should be given as lactate, either undiluted molar sodium lactate, or diluted to one-sixth molar concentration. The proportion of lactate to chloride is appropriately modified when there is already a distortion of the acid-base balance. Many of the causes which lead to massive sodium depletion also lead to significant potassium depletion, but this may not be apparent either clinically or biochemically so long as the extracellular fluid volume is contracted by sodium depletion. As sodium depletion is corrected, the serum-potassium falls, partly because potassium excretion is increased during saline infusion (Wolf 1947) and partly because of expansion of E.C.F. volume. In 1 patient, the serum-potassium fell from 5·6 to 2·8 m.eq. per litre in twenty-four hours, during which a massive saline infusion had been given. My own practice is to give potassium salts by mouth during repair of massive sodium depletion; when this is not possible, parenteral potassium may be justified—a matter to be discussed in the second lecture.

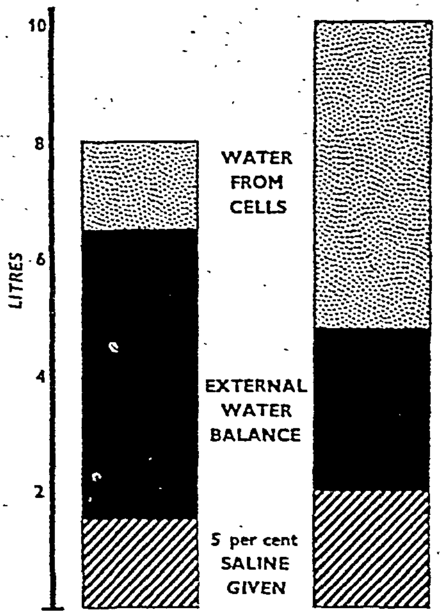

Fig. 2—Comparison of water theoretically required to dilute hypertonic saline down to "normality" with the actual positive balance of water in two patients. The difference represents water mobilised from cells during hypertonic saline infusion.

Perhaps this is as convenient a place as any to point the moral that depletion of sodium, potassium, and water are closely related to each other, and to the acid-base balance, although for purposes both of experiment and of discussion we may sometimes find ourselves forced to impose on them a spurious isolation. When we speak of "sodium depletion," I think we really imply "primary" or "predominant" sodium depletion, for secondary effects very quickly follow any loss of electrolyte or water from the body. Much of the interest of experimental studies in which a specific electrolyte depletion is induced lies in observing the secondary effects on other electrolytes and on water—a theme which I hope to develop in the second lecture. In clinical work, we have the additional complication that most depletions are mixed from their very onset, and we may be hard put to it to discover which changes are primary, and which represent secondary effects. As in most other fields of medicine, responsible experience of the clinical problems creates a healthy distrust of the corpus of knowledge and the intellectual equipment with which we presume to solve them.

"Man is the result of two thousand million years of biological evolution; he has every prospect of an equal or even greater span of psycho-social evolution before him. The human species has many grave problems before it: but it has a great deal of time in which to work them out—there may be some comfort in that thought."—JULIAN HUXLEY F.R.S., Evolution in Action. London, 1953; p. 135.

Repeated serial passages, in Dubos medium, from growth in the highest tolerated concentration of isoniazid failed to produce a strain with an inhibitory end-point higher than 25–50 µg per ml

The level of resistance of ten out of sixteen resistant strains of tubercle bacilli from patients fell substantially during three subcultures in the absence of isoniazid

Mice and guineapigs infected with sensitive strains were completely protected by isoniazid in dosage of 20 mg per kg body-weight daily When mice were infected with in-vitro resistant strains (which showed scanty colonies on solid medium containing 1 µg of isoniazid per ml. and heavy growth on solid medium containing 0 2 µg per ml) treatment with isoniazid considerably increased their survival-time Guineapigs infected with the same strains were almost completely protected, and in guineapigs a chemotherapeutic response is likely even with strains that will grow in the presence of about 1 µg of isoniazid per ml

We are indebted to Miss M Monk for technical assistance The isoniazid used in the in-vitro studies and the experiments on guineapigs was supplied as 'Nydrazid' by Messrs E R Squibb, London

AN OUTBREAK OF STREPTOCOCCAL INFECTION IN A MATERNITY HOSPITAL

JOHN GIBSON
M R C O G, D C H
RESIDENT OBSTETRICIAN

ROY M CALMAN
M B Glasg
BACTERIOLOGIST

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, LONDON

DURING the ten weeks from Nov 1, 1952 to Jan 3, 1953, the laboratory at this hospital received 38 swabs which grew Lancefield group-A β hæmolytic streptococci This is more than the total number of similar swabs received in the preceding five years, and the outbreak is still continuing The relatively small number of times that these organisms were found between 1947 and 1952 is compatible with the decline in the number of patients admitted to fever hospitals with this type of infection Gibberd (1937) suggested that this decline, which was first noted in the period 1935–37, might be in part due to a change in virulence of the prevalent organism This suggestion was based on the observations of Colebrook and Kenny (1936) who showed that the mortality among patients admitted to the North Western Fever Hospital, London, with puerperal streptococcal infections had fallen from 22% in 1933 to 5% in 1936—before the introduction of the sulphonamides —and among the same patients the incidence of peritonitis had fallen from 7 4 to 2 6%

The present outbreak is reported because

(1) It suggests an increase in the virulence of the organism

(2) 4 of the patients, including 1 *infant*, were very ill

(3) A change in the sensitivity to sulphadiazine was observed

(4) It may be a help to other hospitals to be forewarned

On clinical grounds it was difficult to associate some of the cases with the outbreak, and this was confirmed when the result of Griffith typing became available, for it was found that 26 of the organisms isolated belonged to one type while the remaining 12 were *of different types* 26 strains of type 13 (3/B3264) were isolated 1 came from a throat swab and 13 from vaginal swabs of patients, 11 came from throat swabs of nurses and orderlies, and 1 from ward dust

BACTERIOLOGICAL METHODS

The organisms were isolated in most cases from routine high vaginal or *throat swabs* in a few cases intra uterine swabs were taken and the organisms cultured from samples of uterine contents, this method of obtaining specimens will be discussed in a later paper The swabs were spread on blood agar and incubated aerobically for eighteen hours and anaerobically for forty eight hours After incubation the plates were examined and those showing hæmolytic streptococci were subcultured into glucose broth, a plate microscope being used to help in obtaining single colony subcultures in difficult cases A further broth was inoculated with several colonies to obtain, if possible, a profuse growth in eight hours If there was an adequate growth, grouping by a modified Lancefield method was carried out, using organisms scraped from the surface of the plate This direct grouping often gave a satisfactory result which enabled isolation measures to be imposed without delay Occasionally, however, equivocal results were obtained, and in these instances an attempt was made to use the broth with the heavy, but possibly mixed, inoculum to obtain results the same evening If this proved unsatisfactory, the broth *from the single colony* subculture was used for grouping the following morning, this broth was also used to obtain pure cultures to be sent to the Central Public Health Laboratory, Colindale for typing In addition a sensitivity plate was put up by the disc technique, using penicillin (in two strengths), chloramphenicol, and sulphadiazine The sensitivity to sulphadiazine of the type 13 organisms and the other types isolated is shown in table I The majority of the organisms received from the hospital cases were resistant to sulphadiazine, but so far the strains isolated have all shown normal sensitivity to penicillin and chloramphenicol

While the methods described occasionally involved some duplication of work, they identified the group of the streptococcus as soon as possible It was interesting to note that the morphology of the colonies was a very unreliable guide to the group—for example, in one instance an organism was practically non-hæmolytic on aerobic culture and only showed its true β hæmolytic nature on the anaerobic plate, but it was nevertheless a Griffith type-13 strain isolated from one of the severely affected patients The quantity of growth, however, and in particular the presence of streptococci in pure culture were useful guides in assessing the severity of infection

The throat swabs were taken in the usual way with precautions to avoid preliminary gargles or hot drinks The plates were incubated aerobically for twenty-four hours In one case a nurse, who was swabbed as a contact and found to have no streptococci in her throat

always a little lower, in the range of 180/110 to 170/120. Her weight was 182 lb. Biochemically there was again a fall in the serum-sodium level, and there was a slight reduction in the urinary excretion of 17-ketosteroids.

A further period of observation was allowed, lasting for 72 days. During this time the blood-pressure varied between 195/135 and 180/110, and the weight increased to 190 lb. The B.M.R. was −1%. Glycosuria never occurred, but there appeared to be some deterioration of her carbohydrate control mechanism. The mean figures of glucose-tolerance tests and insulin-tolerance tests at this stage are shown in table II. On the 50th day of this observation period a sample of subcutaneous abdominal fat was removed for chemical assay of its D.D.D. content. The wound did not heal for about a month, the delay being presumably due to the high production of endogenous cortisone.

TABLE IV—D.D.D. CONTENT OF TISSUES

Tissue	Date	D.D.D. (mg. per 100 g.)	
		On lipid	On whole tissue
Adipose tissue	Nov. 1, 1951	41	35
,,	Feb. 20, 1952	18	14
Adrenal gland	,,	22	5

For the third course of treatment D.D.D. was given as a 10% solution in olive oil, because arachis oil could not be obtained. The dosage was raised to 5·68 g. of D.D.D. a day, equal to 63·1 mg. per kg. On the 2nd day of treatment she was drowsy. On the 3rd day she was very sleepy and greatly depressed. She complained of headache, giddiness, and nausea, and vomited once. In view of these toxic symptoms the medicine was changed for an equal amount of olive oil containing no D.D.D.; the patient was not told that the active drug had been discontinued. She improved rapidly and was in her normal condition within 2 days. On the 3rd day of this rest period the same volume of a 2·5% solution of D.D.D. in olive oil was substituted for the pure olive oil, the patient thus being given only 1·42 g. of D.D.D. a day, equal to 15·8 mg. per kg. There was a rapid recurrence of the same symptoms as had occurred with the larger dosage. The treatment was continued for 4 days, a total of 23 g. being given in this course. Then, as the toxic effects were continuing, all therapy was abandoned. The patient again recovered to her normal state within 2 days.

After D.D.D. therapy had been discontinued her clinical condition remained unchanged apart from a further increase of weight to 197 lb. On the 76th day after stopping the treatment, nine-tenths of the left adrenal gland was removed by Mr. Philip Hawe. The gland appeared of normal size. Histologically it did not show any atrophy of the deeper layers of the cortex, or any changes suggesting regeneration after previous atrophy. There was no cellular infiltration. Small groups of cortical cells were present in places in the medulla, as is commonly seen in glands from normal people. Part of the adrenal and a sample of subcutaneous fat from the operation incision were collected for chemical assay. Healing of this wound was again slow, taking about 2 months.

After this operation she was given a reducing diet, and after 7 months her weight was 163 lb. At this time her face and abdominal striæ were slightly less red, but the operation wounds were still very red. Her blood-pressure remained in the range of 190/135 to 220/145. A blood-count was normal. The daily urinary excretion of 17-ketosteroids averaged 16·6 mg. The results of a glucose-tolerance test were as follows:

Minutes	0	30	60	90	120
Mg. per 100 ml.	114	183	210	211	143

Slight glycosuria occurred at 90 minutes. The Kepler test showed a good diuresis. The only abnormal finding in the blood chemistry was a high serum-sodium level of 385 mg. per 100 ml.

Biochemical Observations

24-hour specimens of urine were analysed three times a week during the administration of D.D.D. and once or twice a week during the observation periods. We are indebted to Mr. E. Caldecott and Mr. G. Appleton for these laborious estimations.

The technique used for the 11-oxycorticoid estimations was the formaldehyde-chromotropic acid method of Daughaday et al. (1948). This method probably does not measure more than a small fraction of the total 11-oxycorticoids, but the results are sufficiently reproducible for comparative studies of the present type. In this laboratory normal persons give by this method a urinary excretion of 0·3–0·7 mg. per day.

The mean figures of 69 urine estimations and 27 blood estimations are shown in table III. It will be seen that the high output of urine, of nitrogenous excretion products, and of 17-ketosteroids and 11-oxycorticoids was not significantly altered by the treatment. There was no fall in the serum-sodium level during the third period of treatment, possibly because the course lasted only a short time.

Tissue Chemistry

The D.D.D. content of the pieces of tissue was assayed by Dr. F. D. Collins and Mr. G. A. J. Pitt, of the biochemistry department, Liverpool University. Their report is as follows:

“The lipid extracted with ether from the specimens was nitrated, and the colour was developed with sodium methoxide in methanol-benzene mixture according to the procedure of Ofner and Calvery (1945). The intensity of absorption at 600 μ was measured in a photo-electric spectrophotometer and compared with that of D.D.D. which had been similarly treated. Samples of normal human fat, and of the pentothal and curare used at the operation, were examined as controls, with negative results. The findings in the tissues from the patient are given in table IV.

“These tissues contain in addition to the D.D.D. an interfering substance which has a maximum absorption at 500 μ and may be derived from a metabolite of D.D.D. (It is not, however, the same as that mentioned by Ofner and Calvery (1945), which has a maximum at 540 μ.) This has required a correction of the observed absorption at 600 μ; the amount of this correction cannot be assessed with absolute accuracy of the organisms isolated were resistant to sulphadiazine Sensitivity to penicillin was normal The bacteriological methods used are described, and the implications of the outbreak are discussed

We are grateful to Dr R E O Williams and his staff at the Colindale Reference Laboratory for typing our strains, to Dr A J Cashman, registrar in bacteriology, who has undertaken many of the Lancefield groupings, and to Miss J Gratwick for technical assistance

HEXAMETHONIUM COMPOUNDS IN THE TREATMENT OF PRE-ECLAMPSIA AND ESSENTIAL HYPERTENSION DURING PREGNANCY

NORMAN MORRIS
M D Lond, M R C O G
LATE SENIOR REGISTRAR, INSTITUTE OF OBSTETRICS AND GYNÆCOLOGY, POSTGRADUATE MEDICAL SCHOOL OF LONDON

MOST workers agree that hexamethonium compounds will lower the blood-pressure temporarily, and Turner (1951) thought they might prove particularly valuable in the treatment of pre eclampsia and essential hypertension in pregnant women Apart from a recent report by Mulcahy (1952), no serious attempt to determine their value or dangers during pregnancy has been published Accordingly I present an analysis of the results obtained in 10 cases

OBSERVATIONS

As the treatment might involve hazards to the mother and especially to the fœtus, it was in general reserved for cases where the prognosis for the fœtus appeared very poor and where all the usual measures had failed

Administration

Hexamethonium bromide was given either by mouth or by intramuscular injection The summary of case records (see table) shows the high dosage required when treatment was entirely by mouth Even in non pregnant patients the hypotensive dose varies considerably (Mackey and Shaw 1951), probably because of variations in absorption, and during pregnancy absorption is likely to be further impaired In non pregnant patients persistent hypotension (Hirson and Kelsall 1951) and paralytic ileus (Bourne and Hosford 1951) have been reported, and though these complications have *not yet been recorded during pregnancy*, the risk is presumably no less, and perhaps greater, in the pregnant Even a transient hypotension, with its disturbance of uteroplacental blood-flow, might kill the fœtus For these reasons oral therapy is probably

CASE-HISTORIES

Description of case	Maturity at start of hexamethonium	Dose and route	Effect on B.P.	Duration of treatment	Delivery	Fœtus	Hexamethonium estimations
1 Primigravida aged 38 B P at 16 weeks 180/110 Admitted at 21 weeks with B P 180/110 No albuminuria or œdema Poor response to rest and sedation	26 weeks 31 weeks	125 mg, increased to 500 mg by mouth 6 hrly 80 mg intramuscularly 4 hrly, increased to 150 mg 3 hrly	Nil Fair response at first Resistance developed rapidly	6 days 30 days Last injection 3 hours before delivery	Lower segment cæsarean section at 36 weeks	5 lb 3 oz Vigorous at birth Developed cyanotic attacks and died 72 hours later P M widespread purulent bronchopneumonia	Not performed
2 Primigravida aged 22 Admitted at 26 weeks with vaginal bleeding B P 180/140 Urine normal No response to rest and sedation	30 weeks	750 mg–1 g by mouth 6 hrly, increased to 1 75 g by mouth, with 50 mg intramuscularly 6 hrly	Fair response at first Resistance developed rapidly Increased dose gave reasonable control B P 120/80–140/110	20 days Treatment continued till delivery	Spontaneous at 33 weeks	3 lb 12 oz Limp but soon responded Developed signs of intestinal obstruction Transverse colostomy Died on 6th day P M, no explanation except absence of ganglion cells in a narrowed but not obstructed segment of rectum	Not performed
3 Multigravida aged 44 three normal deliveries Admitted at 26 weeks with B P 210/105 albuminuria and œdema Poor response to rest and sedation	27 weeks	1 g by mouth 8 hrly	Fair response Stabilised at 160/100	35 days Treatment continued till delivery	Spontaneous at 33 weeks	5 lb 6 oz Treated in premature baby unit Normal progress	Cord blood at delivery 9 3 µg/ml
4 Primigravida aged 25 Admitted at 34 weeks with B P 140/90, albuminuria and œdema. No response in 48 hours to rest and sedation	34 weeks	250 mg by mouth increased to 1 5 g 8 hrly	Good response after dose was increased	16 days Treatment continued till delivery	Spontaneous after artificial rupture of membranes at 36 weeks	4 lb 15 oz Treated in premature baby unit Normal progress	At delivery amniotic fluid 11 0 µg/ml, maternal blood 3 6 µg cord blood 1 0 µg
5 Multigravida aged 38 two cæsarean sections for pre eclampsia B P at 10 weeks 160/90 Admitted at 33 weeks with B P 190/110 No albuminuria or œdema No response to rest and sedation	34 weeks	60 mg intramuscularly 6-hrly increased to 100 mg 3 hrly	Initially good response Resistance soon developed Increased dose gave satisfactory control	21 days Last injection 15 hours before delivery	Lower segment cæsarean section at 38 weeks	7 lb 2 oz No meconium for 20 hours B P at birth 80/25 Progress otherwise normal	Maternal and cord blood at delivery no hexamethonium detected

METHODS

Sensitivity Tests to Isoniazid

Liquid-medium tests were done in a modified Dubos 'Tween'-albumin medium (Medical Research Council 1948) Serial twofold dilutions of isoniazid in the range 100–0·012 µg. per ml. were prepared in 3 ml. volumes in $^1/_4$-oz. screw-capped bottles. They were inoculated with 0·02 ml. of a culture in the same medium, and the amount of growth was recorded after various periods of incubation at 37°C.

Solid-medium tests were done on Löwenstein-Jensen slopes containing 0, 0·2, 1, 5, 10, and 50 µg. per ml. added before inspissation for 1 hour at 80°C. The slopes were inoculated with a 3 mm. loopful of either a Dubos culture or a suspension of approximately the same turbidity prepared by grinding up growth from solid medium in distilled water. The degree of growth was noted after 14 and 28 days' incubation.

In both methods a control culture of the sensitive strain, H37RV, was tested under identical conditions.

Production of Isoniazid-resistant Strains in Vitro

Resistant variants were obtained either from solid medium containing isoniazid after 6 weeks' incubation or by serial passage through increasing concentrations of isoniazid. This passaging was done by inoculating the series of fluid media used in the sensitivity tests and subculturing from the bottle containing the highest tolerated concentration of the drug into a fresh series of bottles, including one without isoniazid. In this way the degree of resistance was measured at each passage.

Stability of Isoniazid-resistant Variants

The stability of the resistance of the variant was measured by redetermining the sensitivity after one or more subcultures in Dubos medium without isoniazid.

In-vivo Resistance

The in-vivo resistance of the variants to isoniazid was measured in white mice (Schofield strain) and guineapigs treated subcutaneously with the drug.

The organisms were grown in Dubos medium with or without isoniazid. The wet weight of the culture was measured in a vaccine centrifuge tube, and the number of viable units—i.e., clumps of organisms developing into single colonies—was determined by the method of Fenner (1951) using oleic-acid-albumin agar. The mice (17–19 g.), in groups of twenty, were infected intravenously at the two dose levels of 1·0 mg. and 0·3 mg., and guineapigs in groups of six or eight were injected in the right thigh muscle with 1 mg. or 0·1 mg.

Each group of animals was subdivided, half being treated with isoniazid and half serving as untreated controls. Treatment was started immediately after infection and continued until the animals died from the infection or were killed at the end of the experiments. The dose of isoniazid was 10 mg. per kg. body-weight, given at both 9 A.M. and 5 P.M. daily, except on Saturdays, when only one dose was given, and on Sundays, when none was given.

Necropsies were made on the lungs of the mice, and a complete examination was made on the guineapigs. The organisms were recovered from the spleens of the guineapigs of the first experiment and tested for sensitivity to isoniazid.

RESULTS OF IN-VITRO EXPERIMENTS

Variant A

This resistant variant of the H37RV strain was produced by passaging in Dubos medium containing isoniazid; the results are summarised in fig. 1. In this medium H37RV is inhibited by about 0·025 µg. of isoniazid per ml. after 10 days' incubation (Mitchison 1952), but in the first passage growth began to appear in the bottles containing 0·8 µg. per ml. after 39 days and became heavy by 57 days. On the 57th day the growth in this tube was inoculated into the bottles of the second passage and the in-vivo sensitivity was measured in mice and guineapigs (variant A1). The results of the second passage showed that this growth was composed of resistant organisms and not of surviving sensitive organisms which had grown after the destruction of isoniazid during the long period of incubation. After 26 days' incubation the organism growing in 1·6 µg. per ml. of the second passage was passaged a third time, and the growth in the various concentrations showed that there has been a slight increase in resistance. Fourth and fifth passages made after 30 and 29 days' incubation, showed no further increase in resistance.

At the time of the third passage a sensitivity test was made on the organisms of the second passage growing in the medium containing no isoniazid. The result indicated that resistance gained during the first passage was readily lost, for even after this one passage through plain medium the organisms reverted to their original sensitivity. The in-vivo sensitivity of the organisms (variant A0) at this stage was also measured (see below). Similar in-vitro sensitivity tests made from the plain medium of third and fourth passages showed that the strain had become more or less permanently resistant. Finally, the strain from the fifth passage was subcultured seven times in plain medium without any loss of resistance.

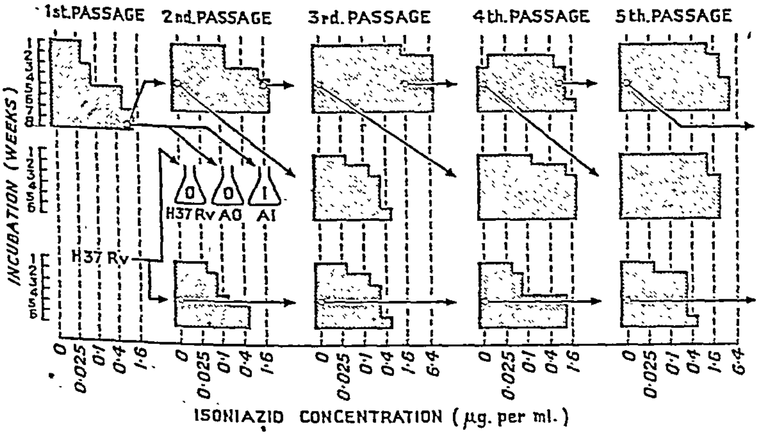

Fig. 1—Results of first five passages of variant A in liquid medium:

Top line: passages in medium containing isoniazid.

Middle line: passages to investigate stability of strains after one subculture in medium free from isoniazid.

Bottom line: H37RV controls.

The flasks illustrate the history of the variants used in experiment 1: 0, no isoniazid; 1, 1 µg. of isoniazid per ml. in medium in flask.

The stippled areas represent growth at weekly intervals in presence of various concentrations of isoniazid. Arrows link the bottles containing the inoculum to the sensitivity tests set up from them. The vertical interrupted lines are drawn at intervals of every two concentrations.

Variant B

This resistant variant was produced independently, but in a similar manner to variant A from H37RV. The period of incubation was 28 days for each passage. In the second and third passages series of bottles were set up not only from the bottles containing the highest tolerated concentrations of isoniazid but also from those with lower concentrations.

The results of the three passages are shown diagrammatically in fig. 2, from which it can be seen that organisms with a slight degree of resistance, produced by one passage in 0·1 µg. of isoniazid per ml., reverted to full sensitivity when cultured without isoniazid. Further, it shows that some of the resistant strains grew very poorly on subculture, suggesting that the and the effect of hexamethonium on these changes could be harmful rather than beneficial

Effect on Labour

In the cases where hexamethonium administration continued during labour it did not apparently alter the normal course

Maternal Side-effects

On the whole the side-effects were not significant All patients had blurring of vision, but they soon became accustomed to this None had severe constipation One showed sensitivity to bromide after two days' treatment, but this disappeared when the drug was changed for hexamethonium bitartrate

Effect on Fœtus

Young (1952) has shown that, in does, hexamethonium passes freely across the placental barrier and can very soon be detected in the liquor If a constant plasma level of hexamethonium is maintained, the hexamethonium content of the liquor increases until very soon it is well above that of the plasma It then persists in the liquor for some considerable period after the last dose has been given If the umbilical cord of the fœtus is tied, then the hexamethonium content of the liquor is very low, which suggests that it reaches the liquor via the fœtal urine Analysis of the liquor in some of our cases tends to support these observations

This accumulation of hexamethonium in the liquor may be of considerable clinical significance From the liquor which it swallows, the fœtus will presumably re absorb a certain amount of hexamethonium The more immediate action of this will be on the intestine itself, and the fœtus may thus be born with a predisposition to paralytic ileus This would explain the two cases in which the child apparently died from this cause and the further case in which there was delay in the passage of meconium This point is still unproven, however, for in a further case, where the hexamethonium content in the liquor was relatively high, the infant showed no ill effect Furthermore Mulcahy, in his series of 10 cases, did not observe any harm to the fœtus

It is also possible that any aspirated liquor would have a somewhat similar effect on the respiratory system, reducing bronchial secretion This may have been an important contributory factor in one case where the infant died from an extensive purulent bronchopneumonia As hexamethonium is only slowly removed from the liquor, discontinuance of treatment twenty-four hours before delivery is expected would do little to prevent these possible complications

CONCLUSIONS

Hexamethonium therapy during pregnancy should not be considered until the customary treatment of pre-eclampsia or essential hypertension has failed and unless the prognosis for the fœtus appears very poor Because of the risk of hypotension and the rather variable response, oral therapy should be avoided With intramuscular therapy the fall in blood-pressure is erratic and unpredictable, though it usually persists for three or four hours Resistance to the drug may develop within a few days

There is no definite evidence that hexamethonium treatment materially alters the course of the disease, but it may help to stabilise the condition It seemed to have no significant effect upon the course of labour

Hexamethonium is known to accumulate in the liquor When swallowed, it may predispose to ileus in the new-born infant and when aspirated it may reduce bronchial secretions and so favour respiratory infection

My thanks are due to Mr J V O'Sullivan, and Dr A S Duncan for permission to include certain of their case records, to Miss I M Young, who made the hexamethonium estimations, and to Prof J C McClure Browne for his encouragement and help in the preparation of this report

CULTIVATION OF TOXOPLASMA GONDII IN TISSUE CULTURE IN MAMMALIAN CELLS

J A Lock
B Sc Lond
OF THE PHARMACOLOGICAL DEPARTMENT, CROOKES LABORATORIES LTD , LONDON

As is known, *Toxoplasma gondii* is an obligatory tissue parasite which cannot be grown in vitro in the absence of animal tissue in the medium Meyer and de Oliveira (1945) and Mühlpfordt (1952) have described the cultivation of toxoplasma in avian tissues, but so far there has been no record of its cultivation in mammalian tissue, though mammals (including man) represent the most important hosts of this parasite

Since this method might be of interest for chemotherapeutic tests and in the study of the life history of toxoplasma, a short account is given of some preliminary experiments, made in 1948, on its behaviour in vitro in mammalian tissue

Methods—Explants of embryonic rat heart were allowed to proliferate on coverslips in Carrel flasks under a fluid medium containing 10% each of rat serum and embryonic extract in Tyrode's solution This method is similar to that used by Hawking (1946) for *Trypanosoma cruzi* After three or four days the tissue was inoculated by the addition to the flasks of a few drops of peritoneal fluid from a mouse infected with toxoplasma Alternatively, the explants were placed in the peritoneal fluid before being fixed in the flasks (Lock 1950) The coverslips were withdrawn at intervals, and the tissue was fixed with Schaudinn's solution and then stained by Giemsa's method

Results—Invasion of the host cells (fibroblasts, macrophages, and probably muscle cells) and the subsequent multiplication of the toxoplasma within them was rapid The accompanying figure shows the appearance of cultures eighteen hours after infection In these preliminary experiments the penetration of cells by the parasite was not observed and mobility of the extracellular parasites was not definitely established Under favourable conditions growth was observed up to ten days, but some cultures with numerous parasitised cells died within forty eight hours This did not appear to be due to the production of excess acid in the culture,

The first four strains were obtained before treatment with isoniazid. The remaining strains were obtained during or after treatment with isoniazid.

The inhibitory concentration of isoniazid is that which permitted the growth of 20 or less colonies.

organisms as were used to inoculate the first flask; thus the strain had been passaged once in the presence and once in the absence of isoniazid. A third flask was inoculated with H37RV as a control.

In the absence of isoniazid, growth of H37RV and its variant A0 began to appear in 6 days, but that of variant A1, growing in the presence of isoniazid, was not visible until 19 days. On the 26th day the cultures were harvested, the wet weights of bacilli were determined, viable counts and liquid-medium sensitivity tests were made (results in table III), and mice and guineapigs (430–690 g.) were injected. The guineapigs each received 1 mg. of bacilli.

The mouse experiment was continued for 50 days, and the results are given in table IV. Isoniazid fully protected the mice infected with H37RV and with the originally resistant culture A0, which according to the in-vitro test (table III) had reverted to full sensitivity, but it afforded only partial protection against 1 mg. of the resistant culture A1.

The macroscopic appearances at the necropsies of the guineapigs killed after 37 days are shown in fig. 3. Apart from that at the site of inoculation and glandular involvement near it in two of the guineapigs injected with A1, there was no macroscopic evidence of tuberculosis in any of the treated animals, whereas the organs of untreated animals were always found to be severely affected. There was the usual histological appearance of tuberculosis in the organs of untreated animals, with early caseation in a few of the tubercles. The organs of two of each group of the treated animals were also examined histologically, and no evidence of tuberculosis was found in any of the lungs or livers, but in the section of the spleen of one animal infected with the A1 culture there were six small tubercles.

Sensitivity tests on solid medium of the organisms recovered from the spleens of the untreated animals showed them to have the same sensitivity as those injected. Only two of the nine cultures from the treated animals yielded growth, and both of these were from animals infected with culture A1; in one culture only one colony grew, and in the other there were only two colonies. The first proved to be as resistant as A1, but the second was slightly more resistant, yielding a confluent growth on 1 µg. of isoniazid per ml., and innumerable colonies on 5 µg. per ml.

Experiment 2

Strains M0, M1, and M2 were obtained from the sputum of a patient with pulmonary tuberculosis. M0 was obtained before treatment with isoniazid, and M1 40 days, and M2 62 days, after treatment with 200 mg. of isoniazid daily had begun. These strains were isolated on medium without isoniazid, and sensitivity tests on solid medium were set up from these primary cultures. Strain M1 was inhibited by 5 µg. of isoniazid per ml., and strain M2 grew well in 50 µg. per ml. Bottles of Dubos medium were inoculated from the control tube of the tests, and flasks of Dubos medium were then inoculated from these bottles. After 13 days' incubation the wet weight of bacilli was determined and a viable count on oleio-acid-albumin agar, with and without 2 µg. of isoniazid per ml., and sensitivity tests on solid and liquid media were set up. Mice and guineapigs (345–460 g.) were infected, the latter receiving 0·1 mg. each. The results of the sensitivity tests (table III) show that there had been a decrease in resistance during the subculturing of the strains M1 and M2, both now being comparable in resistance to variant A1.

The results of the mouse experiments are given in table IV. Isoniazid appeared to give complete protection against the strain isolated before treatment but only partial protection against the two resistant strains. The necropsies on the mice surviving to the 79th day showed that the lungs of the treated mice infected with M0 contained scanty tubercles, whereas those infected with M1 and M2 strains contained numerous tubercles. All the strains had about the same degree of virulence, which was better related to the viable count than to the weight of bacilli injected.

The guineapigs (345–460 g.) were infected with 0·1 mg. of the three strains and were killed after 43 days. The macroscopic post-mortem appearances are shown in fig. 3. Apart from tuberculosis at the site of inoculation and in the local glands, especially in animals infected with M2, and the presence of four microscopic tubercles in the

stoppage of blood-flow through affected vessels when hypotension was induced, and regarded arteriosclerosis as a *contra indication to use of the technique* So were myocardial disease and malignant hypertension, but cases of essential hypertension benefited, and the *circulatory fluctuations arising during removal of a phæochromocytoma* might be more easily managed He felt strongly that hypotension should only be induced if it would be good for the patient It demanded skilful management, especially if it continued into the postoperative period when accidents were most likely to occur

In the ensuing discussion there was some criticism of the number of deaths, and one anæsthetist said he had abandoned pentamethonium because the slightest accident threw the patient into jeopardy. People were also troubled by the suggestion that pentamethonium averted serious surgical shock. In the Manchester neurosurgical unit the drug was used very cautiously in cases of cerebral angioma, vascular meningioma, and aneurysm *just for the 30–60 minutes* when hæmorrhage was most likely, methylamphetamine being given as soon as the risk was past Another speaker mentioned a reflex whereby lowered carotid-sinus blood pressure led to bronchial dilatation, and said that barrel chested bronchitics with laboured breathing often improved as the blood pressure fell during the action of pentamethonium

NUTRITION SOCIETY

The Psychology of Eating

Presiding at a conference held at Aberdeen on Jan 31 by the Scottish Group of the Nutrition Society, Prof **Rex Knight** said that the contributions would illustrate the five main features of contemporary psychology (1) the replacement of anecdote and the literary essay by controlled observation and experiment, (2) the unconscious nature of the tendencies underlying conduct, (3) a renewed interest in the constitution of individuals as opposed to their environmental influences, (4) the emphasis on social factors in the development of personality, and (5) the attempt to relate psychological phenomena to underlying physiological mechanisms

Reviewing the psychiatry of disturbances of eating and of nutrition Prof **W M Millar** said that the relation between the mental disorder and the abnormality of feeding was sometimes obvious, as in vitamin deficiency, but it was more often complex and obscure because it was emotional and symbolic In some mental disorders a loss of interest in life was reflected in a desire *for starvation* and death, in others abnormal fears led the patient to think that food would cause intestinal obstruction Sometimes what began as an eccentricity about food might develop into a way of life—vegetarianism, for example Emotions such as rage and fear had an undoubted though obscure influence on gastric function The rhinencephalon, which was concerned with the functions of central emotion, was capable of accrued, effective, emotional experience which was symbolic, non-verbal, and undiscriminating The rhinencephalon was not closely connected to the cerebral cortex, therefore two independent sets of thoughts could exist In this way intelligent people might be the victims of irrational *emotions and fears* In spite of much careful case taking our understanding and treatment of psychosomatic disorders was disappointing Often the patient had no conscious awareness of the stresses of life which upset his gastric function, the true nature of the relevant stress often remained obscure because neither the patient nor the doctor was willing to discuss the subject

Prof **C F W Illingworth** discussed the psycho*logical* accompaniment of peptic ulceration He agreed that there was undoubted evidence of a connection between the mental state and gastric *function*, but it was not clear how this was causally related to peptic ulceration The published observations *on the* patient Tom recorded that when Tom was defeated his gastric mucosa grew pale and his acid secretion fell When Tom was angry his gastric mucosa became hyperæmic and secreted acid But exactly the opposite results were observed in another patient, Doris, a Negro lady Most patients with peptic ulcers were of a particular temperament and type—tense, driving, active, underweight, possibly obsessional *in some degree* But the relation of this mental state to the peptic ulcer was quite unexplained Many of the mental stresses which had been adduced as causes of *peptic ulcer had been shown* by careful work not to be important—for example mental conflicts of infancy and childhood, the death of parents, unhappy homes, and divorces Perforation *of an ulcer or hæmorrhage might* follow acute psychological stresses, but this relationship was neither the whole explanation nor invariably present During the war, for example, a sharp rise in the incidence of perforated ulcers was correlated with the air raids of *1940–41* on London In Glasgow there was a similar increase in the incidence of perforations but it came just before the raids Moreover, the peaks in the graph *of acute complications of ulcer did not show* in the data for women, who suffered perhaps greater war time stresses than male civilians "We must admit that psychological stress *could* be important *but* we must not overemphasise its rôle, lest we prevent adequate investigation of other influences which might be more important

Dr **C F Rolland** emphasised that anorexia nervosa was a clinical entity but not a very common one In Prof D M Dunlop's wards at Edinburgh Royal Infirmary there had been 25 cases in fifteen years Anorexia nervosa was *the outcome of serious mental* disorder which was neither hysterical nor obsessional Often the mental cause was obscure, but if it could be discovered and explained there was reasonable hope that the patient would respond to encouragement and suggestion He quoted the case of a schoolgirl aged 16 years who was much afraid of her mother When the patient was aged 13 a girl in her school became pregnant and the resulting *scandal made a great impression on the patient* Her own plumpness of figure led to her being teased by her schoolmates to the effect that she too might be pregnant Accordingly she ate little in order to become thin, and by the time she was 16 years of age she had lost all appetite She made a good recovery in response to sympathetic explanation, encouragement, and suggestion Young spinsters were most often affected, and amenorrhœa was a *common and persistent* feature The breasts often remained well developed in spite of the general emaciation Patients under treatment must be carefully watched for tricks such as secreting food, taking cathartics, and deliberately inducing vomiting Concentrated *food* such as *calcium* caseinate *might* be coloured and offered as a medicine, ostensibly *for* the treatment of constipation Insulin, testosterone, adrenocorticotropic hormone, cortisone, and isoniazid were not of value in treatment of this condition

Dr **J M Walker** dealt with the physiological effects of smoking, a subject on which, as he told the meeting the New York City Library had over 4000 volumes Much of the evidence was *subjective, emotionally* coloured, and hard to assess Most studies dealt with acute effects His own paper dealt largely with the effects *on nutrition* When a person stopped smoking his weight increased and his appetite improved Why had smoking *this effect on appetite and weight ? Among other possibly* important effects, cigarette smoking liberated adrenaline and this raised the blood sugar, which reduced sensations *of hunger* Tentatively he suggested that nicotine also acted on the hypothalamus in much the same way as amphetamine, which also reduced appetite *In the light* of this suggestion he was interested to find that the effect of smoking on urinary output after drinking water was to

TABLE IV—CHEMOTHERAPEUTIC EXPERIMENTS ON MICE

Expt. no.	Strain	Infecting dose per mouse		Dose of isoniazid (mg. per kg. per day)	No. of mice surviving on day					Average day survival at 50 or 79 days	Appearance of lungs of survivors

In experiment 1 both treated and untreated mice were also infected with 0·1 mg. and all survived for 50 days.

±, only slightly enlarged.
+, few small tubercles.
+ +, few large tubercles.
+ + +, many large tubercles.

organisms had largely taken the place of the resistant ones during subculture rather than that the resistant strains had poor viability. It should be noted, however, that in only one strain did the culture revert to complete sensitivity.

The experiments on animals show that the three resistant variants A1, M1, and M2 were about as virulent as the original sensitive strains, and that isoniazid did not give complete protection against them. Protection was least in mice. Although treated mice survived the period during which untreated mice died, some of them died later, and the survivors were found to have more tubercles in their lungs than were found in the lungs of the mice infected with the sensitive strains.

In guineapigs isoniazid was more effective, for there was no macroscopic evidence of generalised tuberculosis in the treated animals. Nevertheless the protection was still incomplete, for in the spleens of two guineapigs, one infected with strain A1 and the other with strain M2, there were microscopic tubercles. Further, of the eleven treated guineapigs six had a caseous abscess at the site of inoculation and caseation of the draining lymph-gland, whereas only one of the seven treated animals infected with the sensitive strains had developed a caseating gland, and none had abscess formation.

The partial protection by isoniazid against these resistant strains may be due to the inocula containing only relatively small proportions of organisms capable of growth in the concentrations of isoniazid in the tissues of the treated animals; for the sensitivity tests (table IV) showed that only a small proportion of the bacilli of the strains M1 and M2 could grow in the presence of 1 µg. of isoniazid per ml. Karlson and Ikemi (1952b) and Goulding et al. (1952) have shown that treatment with isoniazid does not affect the mortality or the development of corneal lesions in mice infected with highly resistant strains. Unpublished observations of ours show that strains only slightly more resistant than strains A1, M1, and M2 are at least as lethal in isoniazid-treated mice and guineapigs as in untreated animals. One such strain yielded heavy growth on 1 µg of isoniazid per ml., but no growth on 5 µg, of isoniazid per ml. Therefore it is reasonable to assume that bacilli capable of growth on solid medium containing 1 µg. or 2 µg. of isoniazid per ml. can grow in the tissues of animals receiving 20 mg. per kg. body-weight daily. This dosage is about five times as high as that used in the Medical Research Council (1952) trials but is nevertheless of the same order, and there is therefore some experimental evidence to support the assumption, made in their report, that strains growing in 1 µg. or more of isoniazid per ml. were resistant.

There seemed to be no essential differences between the results of the animal experiments with the three resistant strains, but apparent differences in in-vivo sensitivity in mice and guineapigs are of interest. Gray and Mattinson (1952) have shown that mouse inoculation is more sensitive in detecting small numbers of bacilli than has previously been thought, and they also showed that strain differences in mice were largely abolished if the experiments were allowed to run sufficiently long. Further, Knox et al. (1952) have pointed out that H37RV is much more sensitive to isoniazid at 35°C than at 37°C. The average rectal temperature of mice is 34·3°C (Goulding and Robson 1952) and that of guineapigs 39·1°C (personal observations). The eventual death of mice and the degree of tuberculosis in survivors infected with strains A1, M1, and M2 after relatively long periods might therefore be due to a combination of the long-term lethality of the small number of resistant organisms shown to be capable of growth in 2 µg. of isoniazid per ml. (table I, strains M1 and M2) or to the relative sensitivity of the resistant strains.

It might be argued that, since 10^7 organisms of sensitive strains appear to contain some highly resistant bacilli in vitro, similar in sensitivity to strain B (Rist 1952, Steenken and Wolinsky 1952), the inoculation of as large a dose as 1 mg. of H37RV into guineapigs in experiment 1 would lead to the death of these animals from multiplication of the resistant bacilli, or at least to the production of histologically detectable lesions. However, unreported experiments with strain B indicate that it is virulent to mice but not to guineapigs; so not all resistant bacilli may be able to set up active infection in guineapigs.

It will be interesting to see whether resistant strains of tubercle bacilli from patients treated with isoniazid tend to lose their resistance when treatment is stopped. If this happens in vivo and in manner similar to that in vitro, it might prove of benefit to treat these patients with a further course of the drug, since seven of the sixteen resistant strains which came from patients and were subcultured in the absence of isoniazid had a final sensitivity similar to or below that of A1, M1, and M2.

Finally, a comment on methods of testing the sensitivity of tubercle bacilli from patients can be made. Both Bowen and Collins (1952) and Joiner et al. (1952) have used a technique involving subculture in Dubos medium free from isoniazid before the final test in the same medium. The irregular loss of resistance that is likely to have taken place during such a procedure throws doubts on their results, and one must recommend a procedure using as little subculturing as possible.

SUMMARY

Isoniazid-resistant variants of H37RV produced in vitro rapidly reverted to sensitivity if they had been in contact with the drug during only one subculture. This was confirmed by in-vivo sensitivity tests in mice. Resistant variants passaged more than once in the presence of the drug, retained their resistance without diminution during several passages in drug-free medium.

Resistant variants tended to have poor viability during the first three passages in the presence of isoniazid, but later their viability seemed normal.

against which one should be forewarned are those liable to cause persistent sequelæ or fatalities, such as exfoliative dermatitis and agranulocytosis But we need to know their incidence, and unfortunately Dr Meyler does not give this in most cases He tells us that agranulocytosis may follow diphenhydramine ('Benadryl'), but unless we know whether it is common, or has merely been described on one solitary occasion, we are little wiser The section on acetanilide contains nothing beyond the following

> "cyanosis due to methæmoglobinæmia, hæmoglobinuria, porphyrinuria, irregular pulse, collapse, erythema Prolonged use may give rise to secondary anæmia General malaise, dizziness, palpitations, numb fingers, cardiac insufficiency, anorexia, psychic imbalance, icterus, deafness, hyperæsthesia, increased reflexes, perspiration, nausea, vomiting (Davison)"

This is not of much help Among the many side-effects of aspirin mentioned, without reference to frequency are "damage to the acoustic and optic nerves, even leading to complete deafness and blindness," hyperpyrexia, coma renal colic, necrosis of the liver, and hæmorrhagic exanthemata Often no clear distinction is made between the ill effects that inevitably follow a large dose of a drug—and these are hardly *side*-effects—and those that may follow an ordinary dose

In spite of these defects the book contains much useful information about some drugs If in future editions all the sections are brought up to the standard of the best, the book will be a useful work of reference

Annual Review of Microbiology

Vol 6 Editor Charles E Clifton Stanford, California Annual Reviews 1952 Pp 492 $6

If we have complained of previous issues of this established annual it has been because so much of their contents has been of specialised interest The volume for 1952 contains a majority of reviews which all bacteriologists may read with profit and a few which will interest any member of the medical profession Once a year is not too often for all of us to brush up our knowledge of antibiotics

Sigel's chapter on the influence of age on susceptibility to virus infections is not light reading, but most pædiatricians will find it full of suggestive observations Rickettsial infections and toxoplasmosis have received attention in many parts of the world in the years since the war, and it is useful to have all this work sorted and put in a readable form, and the same is true of Burnet's discussion of virus/red cell reactions But we hope that it is not mere jingoism which causes us to give the palm among all the distinguished contributors to Andrewes's scholarly review of the problems of naming the viruses—*or not naming them* If the standard of this volume is maintained we shall look forward to future issues

Das Inselsystem des Pankreas

Helmut Ferner, professor, Anatomical Institute, Hamburg University Stuttgart Thieme 1952 Pp 174 D M 29 70

Professor Ferner, head of the department of anatomy at Hamburg, here collects in one volume the results of many years' detailed work on the embryology, comparative anatomy, and histology of the pancreas, particularly in relation to the problems of diabetes

He has mainly favoured the Gros Schultze silver method, which can be used only on frozen or celloidin sections, to differentiate the α, β, and D cells of the islets of Langerhans He claims the β α cell ratio determined on sections so stained is characteristically depressed in diabetes, but his hypotheses take him much further He believes, for instance, that the α cells which stain with silver are precursors of β cells, in spite of the fact that mitotic figures in differentiated β cells may be found in suitable preparations Further, he thinks that the anterior pituitary secretes an *alphacytotrope Faktor*, but his evidence for this does not bear scrutiny He also develops an interesting suggestion that juvenile diabetes may be due to a maturation arrest of the transformation of α to β cells, and cites as evidence the absolute increase of α cells as well as the low β α cell ratio in many young diabetics

The book is illustrated by wonderfully detailed drawings of histological preparations, but sceptical pathologists might have preferred a greater proportion of objective photomicrographs There are particularly beautiful illustrations of the blood-supply to the islets of Langerhans

Allergy and Seborrhœa

J Avit Scott, M D, Licencié en Droit (Université de Lille) London H K Lewis 1952 Pp 100 12*s* 6*d*

Dr Scott has attempted the impossible task of comparing a pathological conception of uncertain clinical significance with a group of clinical conditions of vague pathology His disarmingly modest introduction and much of his material suggest that he has written for the beginner—who, however, is more likely to be dismayed than fortified by the greater part of the text It offers difficult and in places exasperating reading even for the dermatologist familiar with the French models upon which it is largely based

A Textbook of Pharmacology

William T Salter, M D, professor of pharmacology, Yale University School of Medicine Philadelphia and London W B Saunders 1952 Pp 1240 75*s*

This book helps to bridge the gap between human physiology and clinical pharmacology Professor Salter has been no more successful than other authors in his classification of the subject matter, but pharmacology when presented for the instruction of medical practitioners is necessarily heterogeneous His book has the merit of consistency—not a conspicuous virtue in textbooks written by numerous contributors

The pleasantly informal style recalls an American statesman's fireside chat, the sections are embellished with appropriate introductory quotations from the poets, and the reader's interest is sustained by clinical reminiscences American idiom abounds, and for the British reader this characteristic in itself makes the book delightful Professor Salter has an enviable capacity for incorporating the gist of original publications into the text without destroying the sequence of his narrative Long lists of references are appended to every chapter, but only a selection of these receive attention in the text The inclusion here and there of short paragraphs on unsolved problems is a stimulating innovation, and the synopses—running to about 200 words—at the end of each chapter will be a godsend to many students and practitioners The writer's views are conventional rather than critical, he prefers the time honoured to the sceptical approach

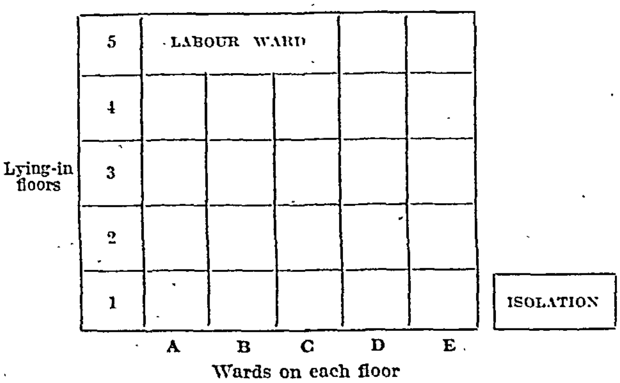
The book is sufficiently comprehensive for both the clinical student and the medical practitioner It might have been more concise and factual, but only at the risk of destroying its attractive flavour

Hypnosis in Medicine

A Philip Magonet, B SC, M D, *president*, Medical Hypnosis Association London Heinemann Medical Books 1952 Pp 104 9*s* 6*d*

Dr Magonet's purpose in writing this account of the technique and possibilities of hypnosis is to encourage doctors and medical students to explore the subject for themselves But his terminology and dogmatic approach are more likely to be acceptable to the layman The prejudice against the use of hypnosis in medical practice, which undoubtedly exists and to which he frequently refers, is unlikely to be broken down by publishing successes and forgetting failures, for the medical reader is trained not to receive suggestion but to consider evidence Hypnosis is in fact already part of the armamentarium of most psychotherapists and there seems little to justify the suggestion that it should be separated from psychotherapy as a whole

After a brief description of the early history of hypnosis Dr Magonet describes his own technique, and then devotes the bulk of his book to cases successfully treated An interesting account of the use of hypnosis in childbirth and in different kinds of insomnia gives an insight into the way in which an experienced hypnotist approaches his subject As an enthusiast for this method of treatment, Dr Magonet feels that the regrettable attitude of the medical profession towards such pioneers as Braid and Elliotson still persists and that hypnosis is still suspect as a field for charlatanry and morbid interest One can at least agree that "employed in a scientific way in accordance with well established principles" its usefulness may increase



developed tonsillitis two days later, and this proved to be due to group-A streptococcus.

HISTORY OF OUTBREAK

This hospital consists of four floors for lying-in patients, each floor having 30 beds which are subdivided into five wards of 6 beds each; the fifth floor comprises the labour-ward suite, and there is a separate isolation ward. The layout is shown in the accompanying plan.

The outbreak started in November with a few sporadic cases, the first being a nurse who reported sick and was sent off duty until her throat was clear. Fourteen days later a baby developed erysipelas and was transferred to another hospital at once. Ten days later another nurse reported sick with a sore throat which was also found to be due to a hæmolytic streptococcus; and in another nurse the organism was grown from a small infected scratch. Despite the considerable interval between these cases and the rest of the outbreak, they were of the same Griffith type and appeared on the same floor. Throat swabs were taken from all contacts, but no positive swabs were obtained, and the ward 2D was closed and disinfected after all other patients had been transferred to the isolation ward. Disinfection consisted of sealing the windows and doors with tape and spraying the ward with 40% formaldehyde; the ward was then left sealed for forty-eight hours before being opened and aired. The technique was described by White (1936) who showed that satisfactory sterilisation could be achieved in this way.

TABLE II—DISTRIBUTION OF CASES

—	1st floor	2nd floor	3rd floor	4th floor
November	—	1 nurse	—	—
	—	1 baby	—	—
	—	2 nurses	—	—
December	—	3 patients	1 patient	1 patient
	—	6 nurses	—	—
	1 case	4 patients	—	—
		1 nurse		
Jan. 1–14	—	—	3 patients	1 patient

Early in December a second group of 5 cases appeared: 3 were in ward 2D, and the other 2 on different floors. Further throat swabs were taken from the staff of the second floor and no less than 6 positive cultures were obtained. All 6 people were sent off duty, and they stayed away until 3 clear swabs had been obtained. The ward was again disinfected.

In late December another 5 cases appeared, 4 of them in the same ward, and the other on the first floor. No more positive swabs were obtained from the staff, but a blood-agar plate exposed in the ward grew a few colonies of group-A hæmolytic streptococci. In early January, 4 more cases were identified in ward 3A, where no positive cultures were obtained from the staff, and an isolated case appeared on the fourth floor. The distribution of cases is shown in table II.

In the early part of the outbreak it seemed that all the connected cases were in the same ward, the reservoir of infection being the nursing staff. After the Griffith typing became known, however, it was obvious that the isolated cases on the first, third, and fourth floors were connected with the main outbreak. If there had been cross-infection between these cases and those on the second floor, it must have taken place either in the large waiting-ward of the labour-ward suite or by way of a carrier among the staff. No evidence has been found to support the first possibility.

The clinical picture was variable, falling into three groups: mild or severe infections of the genital tract, and a miscellaneous group including a case of erysipelas. In 11 of the 14 patients who had genital-tract infections the illness was mild; a typical mild case had a temperature of 100·4°F on the fourth day, which persisted for twelve hours, with little general disturbance and rapid improvement after the administration of penicillin. The other 3 patients, however, were seriously ill for some forty-eight hours, the temperature ranging from subnormal to 105°F associated with rigors. All 3 showed varying degrees of uterine tenderness, a sign which in the pre-sulphonamide era implied that peritonitis was established. The response to penicillin and sulphonamide was much slower than in the mild cases, and the patients remained unwell for two to three days after the temperature had settled.

DISCUSSION

This outbreak of puerperal infections was far larger than anything experienced in recent years and could have been brought about by three main causes:

(1) A relaxation of antiseptic methods.
(2) An increased infection-rate in the surrounding population.
(3) An increase in the pathogenicity of the organism.

The antiseptic routine in the hospital has not been changed during the past five years. There seems to be a moderate number of cases of infection with group-A streptococci in other institutions and in the surrounding district, but the influence of rapid and effective antibiotic therapy on the infection-rate makes it difficult to assess the situation (*British Medical Journal* 1953). On the whole, however, it does not seem that the increase elsewhere is much greater than the normal seasonal rise, and in this connection it is important to note that the patients admitted from the district to the hospital isolation ward all had different Griffith types from the patients who fell ill in hospital. The infection spread from nurse to patient and back, and at the same time the ward dust became contaminated. The difficulty of controlling such a spread while continuing to admit cases, though well known in the past, has been largely forgotten of recent years. One is forced to consider whether the rise in the number of cases, and the severity of some of them, may not be due to an increase in the virulence of the infecting organism, aided by its passage through numerous hosts.

The outbreak continues, and since this paper was prepared we have had 3 more cases; one was mild, another was the most severe genital-tract infection of the outbreak, and the third was a streptococcal meningitis in an infant, the outcome of which is still in doubt. We feel it is important that this epidemic should be brought to the notice of those responsible for other maternity units in order that they may be on their guard against similar severe puerperal infections.

SUMMARY

An outbreak of 25 cases of infection with *Streptococcus pyogenes* occurred in a maternity hospital. The majority

seem to increase the duration of life any further than other treatments, they also used X rays sometimes to reduce the size of the spleen LAWRENCE[11] found that P^{32} was equally effective for chronic lymphatic leukæmia Radiophosphorus is still not much used in this country because of difficulties of supply and handling

Urethane was introduced in 1946 by EDITH PATERSON and her co-workers,[12] and it proved useful especially in chronic myeloid leukæmia STURGIS thinks that experience has shown that results with urethane are inferior to those with radiation, and it is now rarely used, mainly because of the unpleasant side effects—persistent anorexia, nausea, and even vomiting Nitrogen mustard (mustine *B P*) is still much used in this country, many reports suggest that the results are as good as with X rays, and it has the advantage over later modifications that its active phase is relatively short and its effect is therefore more controllable Its great disadvantage is that it has to be given intravenously in a running drip Drugs of this type that can be given by mouth have been introduced[13] PATERSON et al[14] gave one such drug, triethylene melamine, in enteric-coated tablets, and found that its action, unlike that of most antileukæmic agents, was strongest against chronic lymphatic leukæmia Hæmopoietic tissue is, however, very sensitive to triethylene melamine, which must never be used without proper hæmatological control The latest of these antileukæmic drugs that can be given orally is 'Myleran,' accounts of which were given in our issue of Jan 31 by Professor HADDOW and Mr TIMMIS, and by Dr GALTON Myleran is especially interesting because chemically it is quite different from the nitrogen mustards, it is 1 4 dimethanesulphonyloxybutane It is effective only in chronic myeloid leukæmia, in therapeutic doses it depresses granulocyte formation in the bone-marrow without affecting the other elements But, like its predecessors, it is a powerful antihæmopoietic drug that in large doses can cause thrombocytopenia or even pancytopenia Folic-acid antagonists have been used in attempts to control acute leukæmias Some temporary remissions have been obtained with 'Aminopterin,' but the toxic effects can be severe and the results are capricious[15 16] In acute leukæmia A C T H and cortisone have also been extensively tested In a group of 40 cases treated, only 2 had lengthy remissions, 7 more had remissions only during treatment[17] STURGIS points out that the favourable responses that have been recorded were mostly in children

All this activity shows that a great effort is being made to meet the challenge of increasing leukæmia *All the methods hitherto developed need close control,* and the patient's only hope of even temporary relief depends on his attending a centre equipped to deal with the disease

Pneumothorax Therapy

ENTHUSIASM for pneumothorax therapy in pulmonary tuberculosis seems to be waning[1], but this method of treatment is unlikely to be discarded It is a relatively *simple alternative to surgical* measures which few centres can provide for all cases Many clinicians have a certain affection for this method which they can apply at their own discretion without seeking a surgical opinion or transferring the patient elsewhere, pneumothorax may yet prove to deserve in its own right a limited place in treatment Meanwhile, the problem of when to terminate a pneumothorax is still with us

In an attempt to solve this problem HARRIS et al[2] analysed the records at the Edgware and Harrow chest clinics of 279 cases in which a pneumothorax had been abandoned, not because it was unsatisfactory, *but because the* clinician concluded that the disease had been effectively controlled The results, therefore, reflect, not the general value of pneumothorax therapy, but its effectiveness in a selected group of patients in whom things had gone well for several years The investigation showed that no firm criteria had prompted the decision to abandon the pneumothorax There was no correlation between the severity of the initial disease and the duration of relaxation, and whereas some lungs which initially showed only infiltration were kept collapsed for five or more years, others with cavitating lesions were allowed to re-expand in less than three years Some *physicians terminated a pneumothorax only* when refills became too difficult, others when the pneumothorax had been present for five years, and still others on radiological evidence Many clinicians took part in maintaining the pneumothoraces, and no common plan of action could be detected A surprisingly high proportion (46 6%) were badly maintained, and with these the end-results were only *half* as good as with *those* which were *well maintained,* although the efficiency of maintenance was unrelated to subsequent breakdown

HARRIS et al correctly associate faulty maintenance with the staffing of chest clinics, and point out the necessity to keep down the number of patients at refill sessions, in order to give enough time to each patient Another important finding is the disastrous effect of change in personnel among the clinicians Such changes are bad enough when one skilled operator is replaced by another, but they are much worse when an inexperienced locum tenens takes over—which is what commonly happens in clinics at times of holidays or sickness This particular hazard of pneumothorax therapy is seldom recognised It certainly deserves attention, for the results were good in no less than 83 3% where *the pneumothorax was well maintained* YOUNG,[3] also has shown that better results are achieved by a constant operator A system of staffing chest clinics with registrars who are continually changing, often with intervals necessitating the employment of a locum tenens, is clearly not desirable

The investigation emphasises the need for a rational policy with regard to the duration of pneumothorax best avoided, and certainly should not be given to out-patients. Where intramuscular therapy was employed, an initial dose of 20 mg. was given and the blood-pressure was recorded every ten minutes, with the patient sitting up in bed. The dose was then slowly increased until a satisfactory fall in blood-pressure was obtained. The dose thus determined was usually given every three or four hours, provided the blood-pressure was 140/90 mm. Hg or higher. This precaution avoided periods of hypotension. The blood-pressure was recorded hourly by day and two-hourly by night.

Although all but 1 of the 10 patients showed a fall in blood-pressure, this fall never lasted longer than three or four hours and it varied considerably from case to case and from time to time, as has been found in non-pregnant patients (Wĕrko et al. 1951). To maintain a relatively stable blood-pressure was therefore more or less impossible. In most cases resistance to hexamethonium developed very rapidly, often over a period of days; but even when it ceased to lower the blood-pressure, the drug still caused the same degree of pupillary paralysis. This suggested that the autonomic blockade was still in force, but that the hypertension was now being sustained by the increased action of a humoral pressor mechanism.

Effect on the Disease

In the vast majority of cases of pre-eclampsia and essential hypertension, rest in bed and sedation are followed by satisfactory regression of signs and symptoms. Though we were usually able, with hexamethonium, to lower the blood-pressure, it is very doubtful whether this materially altered the ultimate course of the illness. No patient actively deteriorated and none developed eclampsia, accidental hæmorrhage, or gross renal damage, and it is therefore possible that the hypotensive treatment was of some value; but there was certainly very little evidence that the prognosis for the fœtus was improved. In some cases treatment may have been started too late, when extensive placental damage had already taken place; but the vascular changes that occur at the uteroplacental site in pre-eclampsia still remain obscure,

CASE-HISTORIES—*continued*

Description of case	Maturity at start of hexamethonium	Dose and route	Effect on B.P.	Duration of treatment	Delivery	Fœtus	Hexamethonium estimations
6. Primigravida aged 23. B.P. at 16 weeks 120/70. Admitted at 31 weeks with B.P. 150/80 and œdema. No albuminuria. Marked deterioration at 33 weeks. B.P. 170/110, albuminuria, and increasing œdema	33 weeks	100 mg. intramuscularly 4–6 hrly., increased to 250 mg. 3-hrly. (Also given ion exchange resins)	Good initial response. Resistance developed rapidly. Increased dose gave reasonable control. B.P. 140/90–160/100	19 days. Last injection 20 hours before delivery	Lower-segment cæsarean section at 36 weeks	5 lb. 14 oz. Vigorous at birth. Developed abdominal distension and general peritonitis. Died on 8th day. P.M.: peritonitis and distension of intestines with no obvious primary cause	At delivery: maternal blood, a trace; cord blood, none detected; amniotic fluid 5·7 µg./ml. Colostrum: none deetcted
7. Primigravida aged 38. B.P. at 20 weeks 160/100. Admitted at 30 weeks with B.P. 160/105. No œdema or albuminuria. Marked deterioration; B.P. rose to 190/120, with albuminuria	32 weeks	80 mg. intramuscularly 3-hrly., increased to 250 mg. 3-hrly.	No response	48 hours	Lower-segment cæsarean section at 32 weeks	3 lb. 3 oz. Treated in premature-baby unit. Normal progress	Not performed
8. Multigravida aged 28; premature stillborn deliveries in 1946 and 1947. B.P. at 14 weeks 150/90. Admitted at 28 weeks with B.P. 196/130 and albuminuria. No œdema. No response to rest and sedation	29 weeks	60 mg. intramuscularly 3-hrly., increased to 200 mg. 3-hrly.*	Resistance developed rapidly. Moderate response only to increased dose	22 days. Fœtal heart not heard after 18 days' treatment	Spontaneous at 32 weeks	Macerated. Placenta extensively infarcted. P.M.: evidence of intrauterine asphyxia	Not performed
9. Multigravida aged 33; three stillborn infants, with pre-eclampsia. B.P. at 12 weeks 160/90. Admitted at 29 weeks with twin pregnancy; B.P. 190/110 and albuminuria. No œdema. No response to rest and sedation	30 weeks	100 mg. intramuscularly 3-hrly.	Moderate response only	7 days. Fœtal heart not heard after 3 days' treatment	Spontaneous at 31 weeks	Both twins macerated. Infarction of placenta not sufficient to account for fœtal deaths	Not performed
10. Primigravida aged 28. Admitted at 30 weeks with B.P. 140/90–150/95. No albuminuria or œdema. Anencephalic fœtus with hydramnios	32 weeks	20 mg. intramuscularly 6-hrly., increased to 30 mg. 6-hrly.	Good response	14 days	Spontaneous after artificial rupture of membranes at 34 weeks	4 lb. 5 oz. Stillborn anencephalic	See note †

* *Case 8.*—After 2 days' treatment with hexamethonium bromide an extensive erythematous rash developed. This disappeared when the bitartrate was substituted for the bromide.

† *Case 10.*—Hexamethonium was given mainly to determine the rate of accumulation in the liquor:
After 2 days' treatment 30 oz. of amniotic fluid withdrawn, C6 content 0·5 µg./ml.
,, 8 ,, ,, 86 oz. ,, ,, ,, ,, ,, ,, 0·5 µg./ml.
3 days after stopping treatment 20 oz. of amniotic fluid withdrawn, C6 content 4·0 µg./ml
7 ,, ,, ,, ,, 54 oz. ,, ,, ,, ,, ,, ,, nil.

economical to avoid operation and to provide surgical shoes" Each year roughly 40,000 pairs of surgical footwear are provided through the National Health Service, a considerable number of these must be for the broad foot with hallux valgus, so there still seems to be good cause for research into its origin and treatment

Annotations

FOG AND FALLACY

Of our trilogy of reports on the recent London fog (concluded with Dr Logan's paper on p 336) one was from Dr John Fry, who on Jan 31 described the effect of the fog on his Beckenham practice In our correspondence columns this week a Durham colleague, Dr Frank Cort, expresses surprise at the relatively small number of extra visits Dr Fry was called upon to make, compared with his own experience during "a similar occurrence' two or three years ago From this he goes on to point out that the number of visits and attendances per patient per annum is about three times higher in his own practice than it is in Dr Fry's, and that his remuneration per item of service is accordingly about three times less We are glad to print this letter, together with a rejoinder from Dr Fry, because it gives us an opportunity to say, most emphatically, that the value of a practitioner's work cannot and must not be judged by counting his items of service To think in terms of *quantity* is the ever-present temptation of the administrator, but doctors should know better

The truth is that there are many different ways of conducting a general practice efficiently, and practitioners vary widely in their opinion about the frequency with which they need to see their patients Dr Fry's figures suggest that the people on his list are seen by him a little less frequently than the average Dr Cort, on the other hand, prefers to give his Northern patients more than twice as many items of service as are nationally usual But such variations are almost no indication of a practitioner's usefulness to the community indeed they can be interpreted in either direction, according to taste One doctor, by giving his patients ample time when he does see them, by instructing them in simple health and preventive measures, by encouraging their self-reliance, and by discouraging frivolous calls, may keep down the number of items of service asked of him while still providing care that fully satisfies those in his charge Another may find that he likes to give, and that his patients expect and prefer, much more frequent attention Additional factors that may play their part include the differing morbidity in different types of area, and the geographical features and social custom of the district (both of which profoundly affect the frequency of attendance, and the ratio between visits and surgery attendances)

The importance of Dr Fry's figures for the fog lies not in their comparison with other practices but in the variations they reveal in his own practice Dr Fry has achieved a certain pattern of practice which satisfies him and his patients (for he has built and holds a large practice in an area where the average practice is not large) With the figures he has carefully kept, he is able to predict the calls his patients are likely to make on him at different seasons of the year Here in a particular week he finds that he was called upon to give much more than double the number of attendances to patients suffering from respiratory disorders, and affections of the upper respiratory tract, than were needed for the patients of the same practice a fortnight earlier, before the fog descended He has reported this significant fact Similar valuable information, often known to general practitioners but rarely recorded, may well come to light if the College of General Practitioners pursues one of its declared aims—"the encouragement of accurate observation, investigation, and recording of results by general practitioners"

HYALURONIDASE AND URINARY STONES

Last year [1] we remarked on the promising possibility of hyaluronidase as a means of preventing or at least curbing the formation of urinary calculi there is now more news of this interesting subject The story really began in 1950 when Butt [2] observed that subcutaneous injections of hyaluronidase mixed with isotonic saline solution could produce a much clearer urine in patients who had previously been passing a turbid urine containing much sediment The hyaluronidase worked, it was suggested, by increasing the colloid content of the urine and so preventing crystals from forming and growing Indeed, Butt and Hauser [3] were able to give visual proof that an injection of hyaluronidase was followed by the release of protective colloid in the urine, which not only dispersed crystals already there but inhibited the formation and growth of new ones But the addition of hyaluronidase to urine after it had been passed did not increase its colloid content, so the suggestion was made [4] that hyaluronidase acted indirectly by releasing hyaluronate at the site of injection and that hyaluronate was excreted in the urine during the period of restoration of hyaluronate at the site of injection Butt and his colleagues have since shown that potassium hyaluronate is a powerful dispersing agent the evidence suggests, then, that a hyaluronidase substrate is a part of normal urine and that it has much to do with regulating the colloid-crystalloid balance, some disturbance in this balance has for long been blamed rather vaguely for the formation of urinary calculi

Butt et al [5] have now carried their clinical experiments a stage further Before giving hyaluronidase to a patient troubled by recurrent stones, they determined the level of protective colloids in his urine by ultramicroscopic examination and photography, by measurements of surface tension, or by sediment and turbidity tests They then found that in most patients with uninfected urine an injection of 150–300 turbidity reducing units (T R U) of hyaluronidase every 24 or 48 hours produced a considerable increase in protective urinary colloids In the presence of infection much larger doses were needed—often between 300 and 900 T R U and occasionally as much as 2400 T R U daily In this way they were able to suggest a suitable dose for each patient and to control the treatment as it proceeded Indeed, the one discouraging feature of this work is the need to estimate rather carefully the adequate dose for a particular patient, for if too small a dose is given, the colloid crystalloid balance may be tipped the wrong way by sensitisation, and crystal may be deposited rather than dispersed Butt et al do not sound completely happy about this important point, and they are hard at work trying to get to the bottom of it, but if the results they have achieved so far are anything to go by, this question of estimating dosage is not going to prove very troublesome, and moreover, there is no need to worry about giving too much, for large doses of hyaluronidase have no ill effects

Twenty-four patients, who had been forming stones with depressing regularity and for no clear metabolic reason, have been under treatment for from 11 to 21 months All other attempts to subdue the calculi had failed but in nineteen of these patients no new stones have formed and there was no evidence of extracellular multiplication of the parasites under these conditions, although multiplication and liberation of parasites continued in leucocytes introduced with the infecting inoculum from the mouse.

Medical Societies

ROYAL SOCIETY OF MEDICINE

Hypotension during Anæsthesia

ON Feb. 4 the society's section of surgery met under the chairmanship of Prof. F. A. R. STAMMERS, president of the section, to discuss Hypotension During Anæsthesia.

Dr. J. B. WYMAN put the anæsthetist's case for temporarily lowering the surgical subject's blood-pressure by autonomic ganglionic block with a pentamethonium salt. He based his remarks on experience of 1000 major operations, including 157 thyroidectomies and 135 mastectomies; the majority of patients were middle-aged, but 82 were over 70, and 22 under 20.

There were two advantages. Blood-loss was enormously reduced, and this gave the surgeon a clear, almost dry, operating field and shortened his operating time; and pentamethonium seemed to protect the patient against surgical shock. It was known that sympathectomised dogs could not be shocked irreversibly, and autonomic chemical blockade apparently offered similar protection. It was striking how patients remained in a good steady state throughout operations and were in fine form afterwards. He cited 2 cases of hæmatemesis in elderly people where blood-transfusion failed to raise the blood-pressure or relieve shock, but an injection of pentamethonium produced immediate improvement. One of these patients was a man of 80 with an undetectable systolic pressure when his emergency partial gastrectomy was decided on. After 100 mg. pentamethonium his blood-pressure was unchanged but his condition became better; he was discharged from hospital 14 days after the operation. Established shock was clearly not an absolute contra-indication to controlled hypotension, as had at first been believed.

Two risks with pentamethonium everyone had in mind were that it might provoke a vascular accident, or that it might cause a failure of adequate blood-supply to an important organ—which was why asphyxia from any cause was another contra-indication. It seemed, however, that the rate of linear blood-flow through an organ was more important to it than the volume of flow, and was not necessarily altered by hypotension. When coronary flow dropped, so did the work the heart had to do; and the worst that had been noted was a transient depression of the ST segment in some electrocardiographic leads. 114 patients with systolic pressures over 200 mm. Hg, of whom 11 had auricular fibrillation and 1 was in cardiac failure, seemed to do better on pentamethonium than with conventional anæsthesia. There was 1 case of cerebral thrombosis in the series, and there were 3 cases of pulmonary embolism occurring from 10 days to 3 weeks after operation. In general such sequelæ seemed to be unrelated to the hypotension.

Severe renal disease was a contra-indication to the use of pentamethonium, because the drug's excretion might be thereby delayed. The normal kidney went on secreting urine even when the systolic pressure dropped to 60 mm. Hg (as shown by ureteric catheterisation during operation); but there was sometimes transient postoperative oliguria for 24 hours or so, and in such cases intravenous saline would speed up recovery.

Methylamphetamine hydrochloride was usually used as antagonist to pentamethonium; but it was unsatisfactory, because as a cerebral stimulant, it made patients restless, it was easy to overdo the dose, and at the same time its effects might wear off too quickly and it might lead to unnoticed hypotension later. Morphine could be safely used postoperatively even if the blood-pressure was still low.

In this series of 1000 cases 5 deaths occurred—2 from disease, and 3 from faulty technique—before it was realised how heavy were the penalties for the slightest infraction of the anæsthetic routine.

Mr. ROBERT COX said that the surgeon did not realise how much blood a patient might lose in an ordinary operation. By soaking all used swabs and towels in a known volume of water, adding the contents of the sucker bottle, and measuring the final hæmoglobin level for comparison with the patient's preoperative hæmoglobin level, he had been able to calculate this loss. In a thyroidectomy the loss might be 250 ml., in a radical mastectomy nearly 700 ml., in a prostatectomy 550 ml.: if pentamethonium was used the loss dropped to 30 ml. only. Fewer patients needed a postoperative blood-transfusion. After prostatectomies the urine became clear sooner, and in 44 cases he had only 1 with clot retention.

In longer operations lasting up to 6 hours, such as thoracotomies for œsophageal obstruction, he was impressed by the strikingly fit state of the patient at the end of the ordeal. Orthopædic, plastic, and thoracic surgeons among his colleagues also praised the effects of pentamethonium, which helped to speed operations. The risks of postoperative reactionary hæmorrhage and hæmatoma disappeared as soon as the surgeon became accustomed to tying even small bleeding-points. He had found no increase in thrombosis or in renal or liver failure. In the ward after operation patients were nursed in the head-down position until the blood-pressure, recorded half-hourly, began to recover; then they were gradually brought horizontal and then upright. Oxygen had to be available and could settle the restless patient. He had found that phenylephrine was a better antagonist than methylamphetamine.

Controlled hypotension was obviously valuable in increasing the surgeon's view, particularly in operations such as fenestration for otosclerosis where there was usually considerable bleeding. But he felt that the ability of pentamethonium to shield the patient from shock was even more valuable and made its use of very wide application.

Dr. JOHN GILLIES was a proponent of high spinal block—the oldest method of inducing controlled hypotension, and still the most certain one. He pointed out that motor paralysis, sensory block, and hypotension were all obtained with a single injection, which left the breathing largely unaffected and therefore indicative of the state of the medulla. In contrast, intravenous hexamethonium bromide was less certain and its effects were complex. Dr. H. W. C. Griffiths and he had used high subarachnoid block in 802 cases, including 51 partial gastrectomies, 63 urological cases, 341 thoracolumbar splanchnicectomies, and 222 lumbar-sympathectomies. The majority suffered from cardiovascular disease and were poor risks. There had been 7 deaths: 2 on the table, early in the series; 4 from cerebrovascular accidents in patients who had had preoperative episodes; and 1 following reactionary hæmorrhage. 1 patient who developed a coronary occlusion during induction made a good recovery. 3 patients suffered postoperative oliguria, and 7 had transient ischæmia of limbs already affected by vascular disease. He ascribed the latter to an almost complete genicity of the hæmolytic streptococcus Be that as it may, the epidemic illustrates the difficulty of effectively controlling the spread of streptococcal infection while continuing to admit patients Undoubtedly one reason is that the causal organism remains viable in dust for a long time and may defy disinfection with formaldehyde or other chemicals Dust is likely to be especially dangerous if it is being continuously reinfected from a reservoir of streptococci, and the work of Hamburger and others [1] [2] has shown that often a heavy nasal carrier of β-hæmolytic streptococci can be found, and that fresh cases cease when this reservoir is removed Meanwhile, Dr Gibson and Dr Calman are right to warn those responsible for maternity units against the possibility of similar severe puerperal infections

LIVING WITH CANCER

Mrs Edna Kaehele, who has had inoperable cancer for six years, has written a remarkable little book about living with this disease [3] The dust-jacket asserts plainly that the title " does not mean that you can survive for longer than you thought when you have cancer but that, in spite of having cancer, you can live life abundantly " Mrs Kaehele herself, however, has survived for longer than she thought, and believes it has been, in some part at least, a spiritual victory Her story has a special interest, because it may throw some fresh light on the natural history of this disease Most patients who are beyond successful treatment die, as it were, before they have time to rally Mrs Kaehele failed to die at the appointed time, and she has rallied Perhaps her cancer would have regressed in any case, as a few do, but she certainly passed and survived a point at which most patients would have died, and that in itself is interesting

The growth was beyond operation when diagnosed in July, 1946, and by Dec 3 she had received " fifty six X ray treatments, the radium operation, radon implants, as well as biweekly injections of liver extract and countless shots of vitamins to replace the ones destroyed by radiation " She did not feel as though she had profited from this exhausting course of treatment—though it may, in fact, have slowed the *rate of growth of the tumour, and given her body time to manœuvre* Her weight had gone down from well over 10 st to less than 7 st and she had much pain, and hardly strength enough to stand She was given a blood transfusion and sent home on the understanding that she would be dead before the New Year That she did not fulfil this engagement she attributes largely to the determination of her family, and especially of one sister On Jan 17, 1947, as she was still alive, a course of radium chloride therapy was begun "It was tasteless and painless, and when the series was finished seemed to have been useless as well " However, if not gaining she was losing ground more slowly, and in February she was given another transfusion, and received two more in the course of the following months In July, a year from the date of diagnosis, she began a second course of radium chloride treatment, and after that her doctors were at the *end of their resources*

So much for the medical delaying tactics, she does not underrate their value " I beg you," she says to her readers with cancer, "to search out the best cancer specialist you can find and to make full use of the most advanced resources available "

Nevertheless *for a long time after* her treatment ended she remained very ill, and her weight, though she had stopped losing it, remained at 6–7 st She considers she was greatly supported, however, by the general determination that she should live and by her own strong religious faith She was bedridden for a long time, and for several months food "was not only unwelcome but became unbearable " Her family kept her going by adding gelatin to her coffee, and by persuading, bullying, and nagging Then came a turning point, surely of much clinical interest, when she began to eat ravenously, as though the body so recently rebelling against food was now " crying out in starved desperation." Her weight began to rise, and by the autumn of 1947 she was beginning to come " back to life " By Christmas she was going out again and doing her own shopping It was an emotional as well as a physical reorientation, and she naturally writes of it with emotion

She has put on 2 st in weight, and is now engaged in breeding dogs She needs hardly any medication for pain, which is much less insistent To others with cancer she offers two useful pieces of advice have faith in " your doctor, your God, yourself—faith in *something* ", and eat well, " stuff the body with protein to rebuild the ravaged tissues and saturate it with vitamins to revitalise it " On the subject of pain she is reassuring " I must have suffered just about all that one suffers from death by cancer, and I wish to shout it from the housetop *that my greatest* agony was in waiting expectantly twenty-four hours a day for the unbearable pain I confidently expected to begin any minute "

Her message to doctors is probably equally well chosen. If we kill the patient's hope stone dead by inviting him to die at a given time, die he probably will, at the appointed moment, out of a combination of despair and good manners *She also writes feelingly of the American* patient who delays coming for treatment until too late solely because of the expense The National Health Service has surely done a good thing in removing this cause of death from our statistics

STUDENT HEALTH SERVICES

In fact and tradition, students seldom have the means or indeed the inclination to provide themselves with good food and lodgings, and for one reason or another they are often slow to seek medical advice Theoretically, the National Health Service has overcome the student's difficulty *of finding the money to meet* ill health, but, as the Social and Preventive Medicine Committee of the Royal College of Physicians points out in a progress report on Student Health Services published last month this solution does not always work out in practice A student is often not registered with a doctor in the university town because his home is elsewhere, and the National Health Service does not provide for the regular examinations which the committee recommended in 1946 [1] and which are now required by many universities *and colleges To overcome these difficulties, the* committee would like to see more general practitioners fitted into the organisation of student health services, not only to help the student when he is ill in his " digs " but to take on the wider rôle of adviser in health

Looking back on the development of student health services since 1946 the committee finds that the position in the universities outside London, with the notable exception of Oxford, is now largely in agreement with their earlier recommendations in the matters of medical and nursing care, *lodgings, and food* In Oxford certain colleges have their own arrangements, which in some cases amount to an organised health service, but the university recently set aside a proposal for a service covering the student population as a whole The situation in London is unsatisfactory, particularly for the non medical students Nearly all the medical schools insist on regular X-ray examinations, and students can always obtain advice and treatment from members of the hospital staff, but their colleagues in other faculties are often poorly provided *for* True, University College has an excellent scheme run by its student health association, to which the Royal Veterinary College and the London School of Hygiene and Tropical Medicine are affiliated, and Imperial College is also well equipped to look after its students But the other non medical schools and colleges, with a student population of 6000, have done little to follow the committee's advice Most of them delay diuresis but to increase the total volume of fluid excreted. This was not a blood-pressure effect since it was not abolished by hexamethonium.

Discussing the effects of lesions of the hypothalamus on appetite, Dr. C. G. KENNEDY reviewed the knowledge of Fröhlich's syndrome. It was now realised that the obesity, sexual infantilism, and increased appetite did not originate directly from the pituitary tumour itself but from its effects on the hypothalamus. In animals lesions had been made in the hypothalamus by a route which rendered it possible to avoid injuring the pituitary at the same time. Within twenty-four hours the experimental lesion led to an increase in appetite, so that the animal ate twice as much as its littermate control. This was accompanied by the development of marked adiposity. The limit was reached in about fifty days when the total fat of the animal amounted to 70% of its body-weight. If the animal was then starved, the increased appetite returned when it was again offered food. If the food was diluted with inert material, the animal ate enough additional food to make up for the diluent. Small lesions produced experimentally in a site lateral to the hypothalamus could produce the opposite effect on appetite even in rats made obese by an operation on the hypothalamus. Discussing a tentative scheme to explain the observed facts, Dr. Kennedy suggested that the cells of the hypothalamus might be sensitive to chemical rather than to thermal influences, that the feeling of satiety might be conditioned by the cerebral cortex and that hunger might be represented at a lower level than the hypothalamus.

In closing the meeting Professor KNIGHT revealed that the topic for discussion had been suggested by members interested in domestic science who wanted some help with their problem of making certain articles of food more acceptable to children. The outcome of their suggestion was doubtless different from what they expected but he hoped that they were not wholly disappointed.

MANCHESTER MEDICAL SOCIETY

Ulcerative Colitis

ADDRESSING the society's sections of medicine and pathology on Jan. 14, Prof. L. J. WITTS said that although ulcerative colitis had been described by Wilks and Moxon in 1875, modern interest in the disease started from the end of the 1914–18 war. The ætiology of the disease was still unknown, but it was a severe inflammatory disorder of the colon which produced damage akin in degree to a 3rd-degree burn. In about half the cases the illness was chronic and protracted, and few patients went for ten years without a second attack. About 20% of patients died in the first year of the disease, and nearly a third were dead by the end of five years. Complications were numerous and troublesome, and there was evidence of a high incidence of carcinoma after an incubation period of ten to fifteen years.

Medical treatment consisted essentially in rest, a high-protein low-residue diet, and measures to correct malnutrition, anæmia, and depletion of body-fluids and electrolytes. Remarkable effects were claimed for psychotherapy, though this did not as a rule cause resolution of the anatomical changes in the colon. Surgical treatment had become increasingly more radical, and permanent ileostomy together with removal of the colon and rectum was now favoured. It was logical to try A.C.T.H. and cortisone, because of their euphoric effect and their non-specific beneficial influence on inflammation. There was evidence that they might produce symptomatic amelioration, including gain in weight and decrease in diarrhœa; but they likewise did not seem to produce objective improvement in the colon. Professor Witts referred to a Medical Research Council trial of cortisone in which five regions were coöperating, and which should eventually reveal whether the advantages of cortisone outweighed its disadvantages.

Reviews of Books

Text-book of Surgery

Editor: H. F. MOSELEY, M.A., D.M., M.CH. Oxfd, F.A.C.S., F.R.C.S., assistant professor of surgery, McGill University. London: Henry Kimpton. 1952. Pp. 896. 110s.

A great effort has been made in this book to meet the requirements of the modern student. Written by the younger members of McGill University, it has freshness of outlook and vitality. Otorhinolaryngology and gynæcology, as specialties, are omitted, but otherwise it contains all the undergraduate should know. The facts are presented in an attractive fashion by experts in their several departments, and the illustrations are enlivening. Emphasis is laid on the newer developments of surgery—vascular, thoracic, neurological—and this is done to some extent at the expense of the older aspects. Thus, while nothing could be better than the review of the surgical treatment of portal hypertension, which occupies 5½ pages, the very common and still unsolved problem of enlarged prostate is dismissed in a single page. But the whole book is so good that such occasional failures to reach its general high standard can be condoned in a first edition. It will be as popular in this country as it is bound to be in Canada.

Vesalius on the Human Brain

Translated by CHARLES SINGER. London: Oxford University Press. 1952. Pp. 151. 21s.

THIS is the first book to contain a translation into English of any substantial part of the text of that landmark in history, the *Fabrica*, printed in 1543. Before Vesalius, there had been several ineffective attempts to introduce figures into anatomical narrative. But, omitting Leonardo (who failed to publish his researches) no-one had relied on visual impressions for the exposition of a series of investigations. It does not detract from his achievement that Vesalius was not his own draughtsman; for his was the mind that conceived the plan, his the hand that made the preparations, his the voice that directed the artist, his the drive and energy that carried this excessively intricate and difficult research to a triumphant end. Yet this great work has never been widely read. Its text has always been largely inaccessible, even to the learned, and still eludes all but a few: for it is vast, verbose, repetitious, a very torrent of words; its idiom is awkward and conspicuously unsuited to its subject; its format is extremely inconvenient for the student's desk. We can but regret that Vesalius's literary skill did not equal the artistry of some, at least, of his draughtsmen. Dr. Singer in this translation has not attempted to be literal and has avoided many of the repetitions. He selected the section on the brain because it is short and self-contained and clearly shows the state of physiology before the time of Harvey: it is probably the maturest part of the work and makes fascinating reading. He provides an admirable introduction and an instructive series of notes, while the text is illustrated with the *Fabrica's* original figures. The Wellcome Trustees and Foundation must be thanked for making this book available.

Side Effects of Drugs

L. MEYLER, consulting physician, Groningen, Netherlands. Translated by Ph. VUIJSJE and W. MULHALL CORBETT. Amsterdam and London: Elsevier Publishing Co. 1952. Pp. 268. 30s.

Dr. Meyler rightly observes that more and more drugs with possible untoward side-effects are becoming available, and that the doctor should ask himself whether the condition he is treating justifies the risk entailed in prescribing the drug. There is certainly room for a book on this subject, particularly for reference when the prescription of an unfamiliar drug is being considered.

Side-effects which are mild and disappear immediately after cessation of the drug matter little. The side-effects

Public Health

MORTALITY IN THE LONDON FOG INCIDENT, 1952

W. P D LOGAN
M D Glasg , Ph D Lond
CHIEF MEDICAL STATISTICIAN, GENERAL REGISTER OFFICE

The Meuse Valley fog episode in 1930 caused 64 deaths, and the Donora (Pennsylvania) episode in 1948 caused 20 deaths In December, 1952, a four-day fog in London caused about 4000 deaths This paper gives a short account of when and where these deaths occurred, the age-distribution, and the reported medical causes No attempt is made here to present detailed meteorological data or to discuss clinical aspects, these and other features of the incident, including additional details about mortality, will no doubt be discussed in a report which, it is understood, will be made to the Minister of Health when investigations have been completed Two papers have already been published concerning the effects of the fog on hospital admissions [1] and on general practice [2]

TABLE I—DEATHS REGISTERED IN GREATER LONDON FROM WEEK ENDED NOV 15, 1952, TO JAN 10, 1953, COMPARED WITH THE ANNUAL AVERAGE FOR CORRESPONDING WEEKS OF THE FIVE PREVIOUS YEARS, 1947–52

Year	Deaths in week ended								
	Nov 15	Nov 22	Nov 29	Dec 6	Dec 13	Dec 20	Dec 27	Jan 3	Jan 10
1952	1565	1699	1902	2062	4703	3138	2234	2977	2634
1947–52 (av)	1747	1708	1809	1805	1852	1914	1923	2303	2213

The figures given here are from the Registrar-General's weekly returns, with additional data, and indicate that the incident was a catastrophe of the first magnitude in which, for a few days, death-rates attained a level that has been exceeded only rarely during the past hundred years—for example, at the height of the cholera epidemic of 1854 and of the influenza epidemic of 1918–19

INCREASE IN DEATHS

Unusually dense fog developed over practically the whole of the Greater London area early in the morning of Friday, Dec 5, 1952, and continued until early in the morning of Tuesday, Dec 9 In relation to the periods for which the numbers of deaths registered are published in the weekly returns, the fog began toward the close of the week ended Saturday, Dec 6, and continued into the first half of the week ended Saturday Dec 13, and it was in the latter week that the majority of the deaths due to the fog were registered Table I shows numbers of deaths registered in the Greater London area (population about $8^1/_2$ million) from the week ended Nov 15, 1952, to the week ended Jan 10 1953, compared with the annual averages in corresponding weeks of the five previous years Deaths registered increased from 2062 in the week ended Dec 6 to 4703 in the week ended Dec 13 and 3138 in the week ended Dec 20 In the next week (week ended Dec 27) the number of registrations fell to 2234—less than 200 more than in the week before the fog incident It is possible, therefore, that by that time the effect of the fog had more or less come to an end and was not responsible for the subsequent rise in mortality during the weeks ended Jan 3 and 10 On the other hand, part of the decline in registrations in the week ended Dec 27 may have been due to the intervention of the Christmas holidays, during which some registrations may have been postponed It is not possible to be sure, therefore, that all the deaths brought about by the fog had been registered within the two weeks ended Dec 13 and 20 Assuming that they were, the number of deaths so caused can be estimated to lie between 3717 (the excess in the weeks ended Dec 13 and 20 over the week ended Dec 6, 1952) and 4075 (the excess in the weeks ended Dec 13 and 20, 1952, over the corresponding average for 1947–51) Having regard to the opposing considerations that all of the excess deaths in weeks ended Dec 13 and 20 were not necessarily due to fog, and on the other hand that all of the fog deaths had not necessarily been registered within these two weeks, it is reasonable to estimate that in Greater London approximately 4000 deaths were brought about by the fog incident

TABLE III—DEATHS REGISTERED IN LONDON ADMINISTRATIVE COUNTY, BY AGE WEEKS ENDED DEC 6 AND 13, 1952

—	Age							
	All ages	Under 4 weeks	4 weeks–1 year	1–14	15–44	45–64	65–74	75 and over
Dec 6	945	16	12	10	61	237	254	355
Dec 13	2484	28	26	13	99	652	717	942
Ratio of week ended Dec 13 to week ended Dec 6	2 6	1 8	2 2	1 3	1 6	2 8	2 8	[illegible]

TABLE IV—PERCENTAGE AGE DISTRIBUTION OF DEATHS REGISTERED IN LONDON ADMINISTRATIVE COUNTY, WEEK ENDED NOV 29, 1952, TO JAN 3, 1953

Age (years)	Week ended					
	Nov 29	Dec 6	Dec 13	Dec 20	Dec 27	Jan 3
Under 1	3	3	2	2	2	[illegible]
1–44	5	8	5	5	6	[illegible]
45–64	25	25	26	23	24	[illegible]
65 and over	67	64	67	70	65	[illegible]

THE LANCET

LONDON: SATURDAY, FEB. 14, 1953

Leukæmia

LEUKÆMIA, like cancer of the lung, is steadily rising in the table of the causes of death, but—unlike cancer of the lung—it affects all ages, particularly children in the first decade of life and adults after the age of 50. SACKS and SEEMAN [1] point out that the crude death-rate from leukæmia in the U.S.A. rose from 1·0 per 100,000 population in 1900 to 4·3 in 1944, the rate of increase being greatest in the last 14 years of this period. In the U.S.A. in 1942 more people died from leukæmia than from smallpox, meningococcal meningitis, scarlet fever, poliomyelitis, malaria, typhoid fever, and diphtheria combined; each year since 1940 more than 5000 persons have died from this cause. The increase is of peculiar interest to radiologists, since MARCH [2] has shown that, over a 20-year period, this disease is nine times more prevalent in these workers than in the general population. The choice by C. C. STURGIS [3] of the leukæmia problem as the subject of his Minot memorial lecture was therefore timely.

FURTH,[4] who has had as much experience as anyone of animal leukæmia, regards this as a neoplastic disease. "The essential change in leukæmia," he says, "resides in the leukæmic cell and consists of an acquired inability of immature leucocytes to respond to forces normally regulating their proliferation and maturation. This change is essentially that termed neoplastic; the end result is a new type of cell with a wide range of fixed abnormalities as concerns behaviour and appearance." So far as fowl and rodent leukæmias are concerned, there seems to be no doubt about these conclusions. But clinicians are not so sure about the disease in man, and their hesitation has been reinforced by experimental work with human leukæmia: for example, ISRAËLS,[5] whose findings were confirmed by HOOGSTRATEN,[6] showed that human leukæmic cells had not necessarily a fixed behaviour and could mature; and attempts to transmit leukæmia in man have failed. STURGIS remarks that most clinicians have reached two conclusions: firstly, that the ætiology of leukæmia is still uncertain; and secondly, that the balance of evidence at present favours the neoplastic theory. In practice treatment and prognosis are based on this theory.

One feature that has emerged from the animal work is the importance of heredity; susceptibility to "take" a transmitted leukæmia is definitely inherited, and highly susceptible families of mice have been bred. The present view is that the time of appearance and the type of leukæmia depend on interactions of genetic and extrinsic factors. At one time viruses seemed to be responsible for the transmission of leukæmia, but in mice, according to KIRSCHBAUM,[7] virus is not an ætiological agent; it is harboured by the cells of some leukæmic strains and causes an illness which hastens death from leukæmia, and it may alter the antigenicity of the leukæmic cells or the immune reactions of the host. In man familial prevalence is rare; but VIDEBAEK's records from Denmark suggest that there may be some leukæmic families.[8] Another important observation is that of the effect of ionising radiations, such as X rays or those from atomic disintegration. It is well known that leukæmia can be induced in animals by exposure to X rays; we have already mentioned the increased incidence among radiologists; and STURGIS recalls that in people exposed to the atom-bomb explosions in Japan leukæmia developed ten to twenty times as commonly as among the general population.

These findings have not taken us far towards understanding the ætiology of leukæmia. Our ignorance is reflected in the multiplicity of treatments. These are, at present, blood-transfusions, antibiotics, arsenic, X rays, radioactive phosphorus (P^{32}), urethane, the nitrogen-mustard group, folic-acid antagonists, and corticotropin (A.C.T.H.) and cortisone. Blood-transfusion is still much used, especially for temporarily rescuing the patient so that other treatments can be given. Exsanguination followed by replacement-transfusion was tried, but has been dropped; the results were not noticeably better than with a series of ordinary transfusions. Antibiotics have been very useful in controlling infections, especially of the mouth, but they are thought to have no other action. Arsenic, Fowler's solution, was the first of the cellular poisons used against leukæmia, but is now rarely given. Many workers prefer X rays to other forms of treatment; and STURGIS believes that they are still the best remedy for chronic lymphatic leukæmia. It is uncertain whether the radiation should be applied locally to the enlarged spleen or lymph-glands or to the whole body by the so-called "spray" technique. OSGOOD's [9] results suggest that the spray method is preferable. STURGIS prefers localised application for lymphatic leukæmia. He agrees that for myeloid leukæmia the spray technique is the better; but he holds that for chronic myeloid leukæmia radiation by radiophosphorus is the best treatment. LAWRENCE and his co-workers [10] found that in myeloid leukæmia radiophosphorus prolonged freedom from discomfort, but it did not

Deaths in Greater London each day from Dec 1 to 15, 1952

some light on the mechanism whereby the deaths occurred As table VII shows, there was a very large increase in the week ended Dec 13 in the number of cases certified by coroners and in the number of post-mortem examinations In relation to the increased numbers of deaths, however, the proportions of coroners' cases and post-mortem examinations were slightly reduced Cases certified by coroners include only those where referral to a coroner resulted in an inquest or post-mortem examination, the total number of referrals is not known

Number of Deaths Each Day

One of the most striking features of the incident was the rapidity at which deaths started to increase Table VIII shows the number of deaths *occurring* each day (not numbers of registrations as in other tables) Even on Dec 5, the first day of the fog, there was an obvious increase in the number of deaths, and the daily totals mounted rapidly to their highest levels on Dec 7 and 8, the third and fourth days of the fog There was some decline on Dec 9, and a still greater decline on Dec 10, but even on Dec 15 the daily total was almost twice as high as before the fog began (see figure)

PREVIOUS INCIDENTS

The 1952 incident is not the first in which dense fog in London has caused a sudden increase in deaths, as recently as 1948 a continuous but less dense five-day fog was responsible for some 300 deaths in the London administrative county[3] But so far as can be ascertained from a rapid search through the weekly returns, such events have been very rare, and only three others have been traced in which an association between dense fog and suddenly increased mortality has been clear cut In table IX mortality is related to these three incidents and to those in 1948 and 1952 It is evident that the increase in mortality in the 1952 incident was very much greater than on previous occasions

TABLE IX—INSTANCES OF SUDDEN INCREASES IN MORTALITY IN THE LONDON COUNTY AREA ASSOCIATED WITH DENSE FOG

Year	Dates of dense fog	Deaths				
		Weekly totals				Ratio of deaths in week of suddenly increased mortality to deaths in previous week
1873	Dec 9–11	*Dec 13* 1759	*Dec 20* 2415	*Dec 27* 1540	*Jan 3* 1842	1 4
1880	Jan 26–29	*Jan 31* 2200	*Feb 7* 3376	*Feb 14* 2495	*Feb 21* 2016	1 5
1892	Dec 28–30	*Dec 31* 1830	*Jan 7* 2509	*Jan 14* 2503	*Jan 21* 2101	1 4
1948	Nov 26–Dec 1	*Nov 27* 779	*Dec 4* 1019	*Dec 11* 944	*Dec 18* 891	1 3
1952	Dec 5–9	*Dec 6* 945	*Dec 13* 2484	*Dec 20* 1523	*Dec 27* 1029	2 6

There is reason to believe that the fog incident in December, 1952, caused deaths in London on a scale possibly never experienced before from this cause It is to be hoped that such an event will never recur—or be allowed to recur

SUMMARY

The dense four-day fog in Greater London in December, 1952, was responsible for some 4000 deaths during the two following weeks

The increased mortality affected persons of all ages, but particularly those aged 45 and over

Deaths assigned to bronchitis and pneumonia increased eight times and three times respectively in one week

A considerable increase in numbers of deaths occurred even on the first day of the fog

Four previous London fogs resulting in a sudden increase in deaths have been noted, but the 1952 incident caused by far the largest increase

THE FLOODS AND THE HEALTH SERVICES

On Saturday night, Jan 31, a severe gale combined with an unusually high tide to produce one of the worst floods ever recorded in the flat lands bordering the North Sea England, Holland, and Belgium have all suffered severe loss of life and damage to great tracts of land and property Holland has suffered most, the low islands of Zeeland and the mouth of the Scheldt have been almost entirely devastate a tragic

therapy; by pruning out those cases where refills are being maintained unnecessarily long, needless hazards can be avoided, and more time can be devoted to the remainder. Harris et al. suggest that nothing is to be gained by maintaining an artificial pneumothorax for more than three years. This positive statement in a field where the weeds of evasiveness have flourished abundantly for too long can at least be tested by therapeutic trial. Their estimate, which agrees broadly with the findings of Mitchell[4] in his series of 557 cases, seems unlikely to be far wide of the mark. If it were accepted, refill sessions could be reduced not only in numbers but in difficulty, since the difficult refills are commonly those in pneumothoraces of long standing; pricking of the lung, traumatic pneumothorax, and air embolism would thus become less frequent, and there would be less risk of residual respiratory disability from thickened pleura; and the patient would be saved both working time and travelling time. The results would before long indicate whether such a restriction on the duration of pneumothoraces was justified.

Hallux Valgus

Hallux valgus is in the news again; several workers have been making further attempts to eludicate the ætiology of the condition and to assess the value of various operations. There have long been two chief contenders for the causative crown: tight, wrongly shaped shoes, and metatarsus primus varus. Undoubtedly, however, hallux valgus is found occasionally in people who have never worn shoes, and quite often in people who have always worn "sensible" shoes; and as to metatarsus primus varus, Hardy and Clapham[5] conclude from an extensive survey of children aged 4–15 that "the deformity of hallux valgus *precedes* widening of the first intermetatarsal angle. A congenital widening of the first intermetatarsal angle may not be as important in hallux valgus formation as had been thought." Hardy and Clapham also make interesting observations on the lateral displacement of the distal phalanx on the proximal phalanx, which might be of primary importance in initiating the deformity; and they suggest also that there is need to investigate the function of the abductor hallucis—which makes one wonder how many of us (or our children) can actively abduct our big toes from the remainder. Surveys of peoples who go barefoot may throw further light on the problem; but meanwhile there is commonly no apparent cause whatever for hallux valgus.

Conservative measures do little or nothing to halt this progressive condition, and eventually many patients undergo operations the results of which are far from satisfactory to the discriminating surgeon. Bonney and Macnab[6] have made a critical survey of the results of operation for hallux valgus and hallux rigidus at the Royal National Orthopædic Hospital. As usual the patients were predominantly women; and, like Cleveland and Winant,[7] these workers think that this is partly explained by the greater willingness of men to wear suitable shoes. They show that in patients with a family history of this trouble symptoms appear earlier than in others. Most of their patients had increased intermetatarsal angles, and they assume that this is a primary defect. In the adolescent osteo-arthritis of the joint is not a major factor; and the various arthroplasties, all of which leave the toe somewhat weakened, are obviously far from ideal. The solution might seem to be to do an osteotomy at the base of the first metatarsal; but Bonney and Macnab list many causes of failure. It is remarkable that "in 34 of the 54 feet operated upon the metatarsus primus varus returned to its original state or to a larger angle than before operation after intervals varying between one day and three months after operation." The main technical difficulty after osteotomy is to maintain the correction, and in some cases a screw was passed through the neck of the first metatarsal into that of the second, to maintain the position. (Bonney and Macnab do not mention the simple and satisfactory method by which a suture is passed around the two metatarsal necks.) Even theoretically, however, a metatarsal osteotomy is not fully satisfactory; it would seem that one should either correct the hallux valgus itself at the same time by the appropriate soft-part operation, or, accepting the deformity at the joint as permanent and best for future joint function, do a double osteotomy—one at the base to correct the metatarsus varus, and one at the neck angled in the reverse direction to correct the hallux valgus. A double osteotomy can in fact give very satisfactory results. In adults the theoretical advantages of the single osteotomy have not been confirmed in practice; and Bonney and Macnab point out that this operation "involves placing the articular surface of the first phalanx in relation to an area of the metatarsal head which through long continued subluxation is usually denuded of cartilage"—which is of course the reason for doing a double osteotomy. They conclude that with the single osteotomy the results had been unsatisfactory because of imperfect technique and inadequate selection of patients. Like others, they found that the arthroplasties of Keller and Mayo often gave a good result; but sometimes it was unsatisfactory, and they investigated possible causes of this—including selection of cases, operative technique, and after-treatment—without finding any clear lead. They confirm Lloyd's[8] finding that the functional result was equally good with either form of arthroplasty.

There are of course other procedures, and Ross Smith[9] commends arthrodesis of the first metatarso-phalangeal joint in 30° of dorsiflexion. Immobilisation must, however, be continued for a long time; and his results are no better than those in the best arthroplasty series. No matter what method is used there is still an unpleasantly high proportion of failures either from recurrent deformity and pain, or from interference with the function of the foot as a whole causing metatarsalgia or other troubles. Bonney and Macnab rather gloomily remark that no operation on the hallux valgus will enable the patient with a very broad foot to wear ordinary shoes; "in such a case it is probably wiser and more

RESEARCH AND MENTAL HEALTH

LAST WEEK'S CONFERENCE IN LONDON

NOWADAYS in our society the child often finds himself rare, precious, and in the way Dr MILDRED CREAK (physician to the department for psychological medicine, at the Hospital for Sick Children, Great Ormond Street) drew attention to this juvenile predicament at the annual conference of the National Association for Mental Health, held on Feb 5 and 6, with Prof C FRASER BROCKINGTON presiding

Recent Advances in Theories of Child Care

The small family, the small house, and the multiplication of ageing adults, Dr CREAK said, bring new problems in interpersonal relationships In some ways the child is getting a better start than he did earlier in the century She mentioned the change which is coming over the conduct of confinement in hospitals At one period, especially in the United States, there was a strong move to separate the mother and the child, and to substitute artificial feeds, prepared to a precise formula, for breast-feeding The accoucheur and the nurse were the prima-donnas of the performance, and when the mother was allowed to take her baby home she hardly knew how to bath him Opinion has now swung over, and in one American clinic the baby sleeps by his mother, and is fed when he demands it Similar research is also going on in London—with one group of babies fed according to the clock, and another group fed on demand—to determine which babies do better, and which method throws more strain on the mother Dr Creak recalled the observations of Bowlby on the stunting of emotional growth of infants produced by deprivation of the mother, and the persistence later in such children of infantile characteristics they are apt to lack initiative, and to concentrate poorly, their interest being of a superficial flitting kind She discussed the new move to allow more visiting by parents when children are in hospital, and mentioned the film[1] made by Dr René Spitz which shows the damaging effects of long term deprivation on infants in residential care Of nursery schools and day nurseries (now likely to be cut down) she said that, while experts are sure his own home is the best place for the young child, mothers are equally sure they need day-nurseries and nursery schools—largely, she believes, because homes are nowadays so small The maternity and child welfare centres, which greatly help the mother of the pre school child, are nowadays reinforcing their staffs, in some places, with a psychiatrist and a psychiatric social worker, and child-study centres in London and Leeds are studying the normal child The difficulty is that the various bodies giving the mother advice are apt to have various outlooks The maternity and child-welfare clinic, the nursery school, the primary school, and the child-guidance clinic are all differently oriented towards the child, and even the Government departments responsible for children—the Ministry of Health, the Ministry of Education, and the Home Office—*do not* necessarily speak with one united voice She spoke with feeling of the "creeping crushing emergency" of growing lists of psychiatric patients at our hospitals and clinics, and mentioned the debt psychiatry owes to psycho analytic theory, which has drawn attention to the significance of early parent child relationships Many new lines of research are converging on mental health If they are to be brought cooperatively to bear on it, the keynote must be successful communication among researchers

Miss A M SCORRER (chief inspector in the children's department of the Home Office), speaking of children under residential care, mentioned the problems created by rising numbers, old buildings, and the need to find ways of preventing children from coming into care, and of restoring them as soon as possible to their families Hearing the many opinions nowadays voiced on child care, she remarked, made her grateful for the resilience of children She noted that whereas in 1948 at the time of the Children's Act, we were all talking of "deprived" children, we are now more inclined to talk of children "in care," which suggests at least that we are paying more attention to the need for care, and the circumstances which put children in the position of needing it At a recent date there were 63,000 children in the care of local authorities in the country, and during the year preceding this date 36,000 came into care and 33,000 went out of care Over half of them were under five, and 46% of the girls and 39% of the boys were boarded out—nearly a quarter of them in family group homes She reminded the conference that not every deprived child will develop a pathological state later, or *needs to be brought up in the expectation that it will It is not possible to provide a complete substitute for a normal home life, or to prevent serious emotional effects in some cases, but it is possible to provide, for many children, effectual substitutes for home life* Thus in residential nurseries there is now a system of arranging that nursery mothers shall be personally responsible for three or four children Adoption is arranged when possible and there are more adopters than children to be adopted Boarding out with ordinary families is also widely used, and "home groups" are formed, made up of children of various ages and both sexes, who live in an ordinary house with a "home" mother and father, and go out to the ordinary school and join in ordinary neighbourhood pursuits This often works well, but when the child grows up and leaves he is unlike other young people in that he no longer has the family home behind him to return to at a time of stress He is therefore encouraged to make friends in the neighbourhood while he is still in care, and often these friends take the place of uncles and aunts, or other relatives

Miss E N BARTLETT (psychologist to the Essex Education Committee), discussing the application of recent theories to the education of children at school, mentioned the lag between the acceptance of a theory by experts and its application in practice by ordinary teachers Most teachers (like most psychologists), she said, are ordinary and their practice is limited by external conditions in the form of administrators, architects, and epidemics When half the children are away with measles she has often noticed the improvement—the release and optimism—in the affected class A teacher dealing with 55 eight year olds in a classroom meant for 40 is rightly sceptical of the intelligence of those who advocate such things as more personal attention, coaching for the backward in small groups, and special and sensitive handling of the maladjusted child The most effective thing for the psychologist to do in these circumstances is to try to establish among teachers a climate in which new ideas and attitudes will flourish, and in fact the climate is slowly changing to one favourable to such ideas Many things hamper the change Thus the young teacher, fresh from college, and full of ideas of treating children as persons, may be so poor a hand at managing a class that she does not give the children confidence she may excite hostility, and respond with hostility, and even become permanently hostile, and she will find plenty of tired colleagues to point the moral Again, she may understand the new ideas imperfectly—for emotional as well as intellectual reasons The good young teacher, with good luck, may develop into the good experienced teacher, with bad during the hyaluronidase period, and in four of them existing stones have become smaller and less dense radiologically. At least some of the five failures, it seems, may have been caused by incorrect administration of the drug. During the experiment no other form of treatment was used. Most patients had an injection every 24–48 hours; and Butt et al. point out that the site of injection should be changed so that the same area is not injected more often than once in 4 days. Frequent injections are clearly a drawback; but if they can really help a patient threatened by recurrent stones, then he will accept the irksome routine as cheerfully as most diabetics do.

TREATMENT OF SLEEP PARALYSIS

SLEEP paralysis is a rather rare disorder of the normal change of consciousness from waking to sleeping or sleeping to waking. It seems to be rather commoner on waking than on falling asleep, although the so-called night-nurse's paralysis may possibly be predormitial sleep paralysis. Those who experience this disorder say that they are quite conscious and their sensory powers are complete, but they are unable to move or speak. This rather frightening state may last for as long as ten minutes. Sometimes sleep paralysis is associated with narcolepsy.[1]

Our understanding of sleep itself makes little headway. Some attribute sleep to general cortical processes, and others to the special action of a localised area of the posterior hypothalamus which is variously regarded as a waking centre, a sleep centre, or even a combination of these two. Narcolepsy and hypersomnia arise in association with many different organic conditions of the brain, but structural involvement of the hypothalamic region is generally regarded as the commonest cause. This does not necessarily prove, however, that we owe ordinary sleep to the hypothalamus: for the sleep of narcolepsy and of hypersomnia may differ from the physiological form.

Weitzner,[2] who has successfully treated sleep paralysis by insulin hypoglycæmia, obviously has no doubt that it is the hypothalamus—be it sleep or waking centre—that is involved in this syndrome; he asserts that insulin hypoglycæmia increases the power of the hypothalamus to regulate sleep, and he recalls that usually one of the first benefits that patients with rheumatoid arthritis derive from treatment by insulin hypoglycæmia is a relaxed and uninterrupted night's sleep. Weitzner's ideas will perhaps not be accepted by all; but his findings may form a useful basis for further observations.

A SUBSTITUTE FOR LYSOL

OF the disinfectant compounds derived from the distillation of coal-tar at rising temperatures, phenol has the lowest boiling-point and is most highly destructive to tissue. It is followed by the cresols, which are much more bactericidal and rather less toxic; being less soluble, they are put up in solution in soap. Lysol, which is a 50% solution of cresols, has a wide range of activity on bacteria and fungi, and has long been popular as an economical disinfectant for general use. It has the disadvantage, however, that its bactericidal value varies with the different oils and fatty acids which may be used in its preparation. Furthermore, it has an irritant or even necrotic action on the skin. Leonard Colebrook, who observed this with concentrations necessary to destroy the hæmolytic streptococcus, condemned lysol for midwifery and suggested that chloroxylenols should be used; these, however, have only a limited action on staphylococci and *Pseudomonas pyocyanea*, and they lose much of their value when organic matter is present.

The skin irritation from lysol is due to the cresols contained in it; and refractionation of the higher phenolic homologues will yield a fraction or "cut" which contains no cresols but is close enough to them to give, when formulated, a disinfectant with most of the desirable qualities of lysol and, in effective concentrations, no damaging action on the skin. The properties of a material of this sort, marketed as 'Sudol,' have been investigated by Finch.[1] It contains 50% of phenols, and a blend of vegetable fatty oils is used as the basis of the soap. It forms a clear solution with distilled water and gives a slight opalescence without scum in tap-water. Its activity against seven representative bacterial species—mainly pyogenic and intestinal organisms—was compared with that of carbolic acid in Rideal-Walker and Chick-Martin tests, and with lysol and the solution of chloroxylenol *B.P.* in modified tests with and without organic matter.

We have already noted the serious limitations of these tests.[2] The comparative figures reported by Finch seem, however, to show clearly the greater bactericidal effect of the lysol substitute, and its greater activity against non-sporing organisms in the presence of organic matter, especially when compared with chloroxylenol solution. In working concentrations, and even for a few minutes undiluted, it does not burn the hands. Further work will no doubt be done to assess its value as a skin disinfectant, and, diluted with equal parts of water, for such purposes as the sterilisation of instruments and baths. The fraction has no doubt been carefully selected to exclude the known carcinogenic components of the distillates. This precaution has to be kept clearly in mind in the search for better disinfectants among the higher "cuts."

THE RESURGENT STREPTOCCCCUS

IN the past two decades the outstanding successes of chemotherapy against bacterial infections have perhaps lulled us into a false sense of security. On an earlier page of this issue will be found an account by Dr. Gibson and Dr. Calman of an outbreak which shows us that the hæmolytic streptococcus has not lost its sting.

Between Nov. 1, 1952, and Jan. 3, 1953, the laboratory at Queen Charlotte's Hospital received 38 swabs from which group-A β-hæmolytic streptococcus was isolated. It was found that 26 of the strains isolated belonged to serological type 13 (3/B3264): of these, 1 came from a throat-swab and 13 from vaginal swabs of patients, 11 were from throat-swabs of nurses and orderlies, and 1 was from ward dust. The first recognised case of streptococcal infection was in November, 1952, when a nurse complained of sore throat. She was sent off duty until her "throat was clear." A fortnight later a baby developed erysipelas, and although this baby was immediately transferred to another hospital streptococcal infection appeared sporadically in patients and staff. At first all the cases were in one ward, but later cases occurred in wards on other floors. By last month it was evident that the epidemic type of β-hæmolytic streptococcus (type 13) had become well established. In 11 out of 14 infected patients the illness was mild; the other 3, however, were acutely and seriously ill with temperatures of up to 105°F with rigors. Of 3 later cases 1 was mild, 1 was the most severe genital-tract infection of the whole outbreak, and 1 was a streptococcal meningitis in an infant who was critically ill.

Dr. Gibson and Dr. Calman emphasise that "this outbreak of puerperal infection was far larger than anything experienced in recent years." They give reasons for thinking that it was not due either to relaxation of antiseptic methods (which have not been changed in the last five years), or to an increased infection-rate in the surrounding population. They are inclined to think that the great increase in the number of cases and the severity of some of them may herald an increase in the patho-

CORPORAL PUNISHMENT

HOWARD LEAGUE MEETING

A PUBLIC meeting was held at the Caxton Hall on Feb 3, under the auspices of the Howard League for Penal Reform, to protest against the reintroduction of corporal punishment which is proposed, as an amendment to the Criminal Justice Act of 1948, by a Private Member's Bill due for its second reading on Feb 13

Mr KENNETH YOUNGER, M P, who was in the chair, said that he regretted the proposal to reverse so soon a measure of penal reform which had been the subject of most controversy during the passage of the Act of 1948 Indeed, this clause had been responsible for the only division of the House on the Act, and it had been referred back to the Commons by the Lords—chiefly at the instigation of judicial and ecclesiastical peers

Mr GERALD GARDINER, Q C, who spoke on Corporal Punishment as a Deterrent, reminded the meeting that one of the two main objects of the Howard League was to reduce crime He could only speak as a lawyer, and say how he thought this could best be achieved At first sight the case for corporal punishment might appear incontrovertible there was an increase in crimes of violence and we all felt sorry for the victims and wanted to stop the crime wave, if corporal punishment would do this, let us have it back It had been found in the past, however, that legislation passed in haste in response to popular agitation, such as that stirred up by the current press campaign, was often proved later to be wrong There was some exaggeration by opponents of corporal punishment about the effects of the "cat", when administered under strict medical supervision only about 2% of the men flogged had to be admitted to hospital On the other hand, the protagonists of corporal punishment tended to minimise the effects of birching

The only thing to do, Mr Gardiner said, was to examine the facts, and he had yet to meet a supporter of corporal punishment who had taken the trouble to study the relevant documents—carefully collected by the Cadogan Committee in 1938 This committee had come to the conclusion that flogging and birching differed very little in the pain they inflicted, and they had examined the history of punishment, studying its effects during the preceding thirty years They had also considered the history of all offenders convicted of robbery with violence (practically speaking, the only offence for which flogging could be awarded), and they had found that the subsequent history of men who had been flogged was worse than that of men who had not been flogged This could not be explained on the grounds that only hardened offenders had been flogged, for the same applied to men flogged for a first offence More of the men awarded corporal punishment committed further offences, and more than twice as many committed robbery with violence again The committee had also examined the claims that corporal punishment had put a stop to garrotting in London in the 1860s and to the other outbreaks of crime In none of these instances, often quoted by supporters of flogging, was this claim substantiated Experience in Scotland, where flogging was stopped in the 1860s, also refuted the argument that corporal punishment had a deterrent value, for the decline in crime in that country had been greater than in England, where flogging was retained until 1948 No civilised country in the world outside the British Commonwealth retained flogging as a penal measure, except the States of Delaware and Maryland in the U S A

The efficacy of corporal punishment as a strong deterrent had always been strenuously maintained by judges, but Mr Gardiner felt that judges were in no way qualified to form a valid opinion The people who were deterred from committing crimes never came into court What deterred the average citizen was his own conscience and sense of moral values, at the other extreme, there were people so antisocial that nothing would deter them The wobbler in between might or might not commit crime, depending on his awareness of a deterrent or its lack For such people, he was convinced, the probability of detection constituted a far more cogent deterrent than the nature of the punishment It was much to be regretted that our police force was now 10,000 under strength, and that the rate of conviction, which before the late war was 75%, was now just under 50%

One class of criminal, the aggressive psychopath, tended to commit the most brutal crimes because of his callousness and lack of conscience, and the "short sharp punishment" of flogging combined with, say, six months in gaol would mean that such a man was returned to the community in the same state within a very short space of time For such cases we needed something between a prison and a Broadmoor, but the longer sentence of preventive detention provided for under the 1948 Act was not being given a chance to prove itself, because of shortages in prison staff and buildings

The Rev DONALD SOPER, PH D, speaking on the Ethics of Corporal Punishment, said that in this country, professedly Christian, the ethics of any punishment should be Christian ones He was not one who disregarded the doctrine of sin and human responsibility, he did not subscribe to modern ideas which attributed all crime to disordered glands, difficult circumstances, or bad government So long as there were sinners, there would be crime, and crime had to be punished The aim of punishment from a Christian viewpoint must be reformative It was often said in favour of corporal punishment for crimes of violence that it was making the punishment fit the crime, he would say rather that it was making the punishment resemble the crime—and psychologists would say repeat the crime

The Christian regarded the criminal as one of the children of God, and therefore of immeasurable worth as a human being Lack of consideration for his individual value was on the road to the totalitarian outlook In his experience of more than twenty years as a prison chaplain, Dr Soper had not come across one criminal whom he had found unworthy of consideration as an individual He thought there was no evidence that corporal punishment reformed a man, it might harden him or cow his spirit, it was the exemplification of the doctrine "an eye for an eye ," expressly repudiated by Our Lord Moreover, it was a topic that invariably aroused strong emotions Why did everyone get in a fever when they discussed it? Surely because it was so closely bound up with the sexual element, the sadism and the masochism latent in all of us He had seen men flogged, and he remembered a man who undoubtedly got erotic satisfaction out of being flogged, and moreover he had heard flogged men talking of this afterwards Similar ignoble emotions were stimulated in the officials who had to administer the flogging It was a form of punishment which degraded both the recipient and the administrator

The argument was sometimes used that some criminals could only be got at by physical pain To do so, Dr Soper thought, was merely to confirm the criminal in the methods of violence he had himself used People like Craig and Bentley were products of a pagan world in which the individual felt lonely and unwanted and sought his satisfaction in power and excitement To reclaim such individuals we needed a form of punishment which had love as its motive—not sloppy sentimentality but the realisation that these individuals were frustrated and lost and needed to be brought back into the family of the community where they would find a place and feel wanted and valued for themselves Corporal punishment belonged to our modern world which had given itself over to violence, and unless we were prepared for sacrifices, such as spending money on our prisons, and for a make use of mass-radiography units, and some have part-time nurses, but other provisions are scanty or non-existent. The colleges which seem reluctant to act justify this situation by saying that there is no demand from the students themselves for anything better or that there is no need for any arrangement outside the National Health Service. One reason for this inactivity has certainly been the absence of any financial provision for student health in the previous five-yearly estimates, and the committee hopes that allowance has been made in the 1952–57 estimates. Moreover, the lack of progress in London may be partly due to the separation of the medical schools from the other schools and colleges: as the committee points out, where this separation is slight—at University College—the students have a first-class health service.

The extension of student health services has also been urged in the past by the Goodenough Committee, by the several conferences on student health held since the war by the Nuffield Provincial Hospitals Trust, and by the students themselves through the National Union of Students and the British Medical Students Association and in other ways. And clearly much has been done in response. But it is surprising that in so many of the London colleges these authoritative opinions have been largely disregarded. If the reason is financial, the answer is that it is false economy to save money at the expense of health; if it is one of principle—based on the claim that a responsibility no longer exists—then the committee of the Royal College of Physicians has pointed clearly to the fallacy.

SUBACUTE INCLUSION ENCEPHALITIS

CONSIDERABLE progress has been made in the differentiation of a number of types of virus encephalitis, which, both clinically and pathologically, falls into fairly well-defined groups. Apart from those following vaccination and infections such as measles, influenza, and mumps, Greenfield [1] recognised four main divisions:

(1) Acute polioclastic encephalitis, where an acute inflammation affects mainly the grey matter.

(2) Acute hæmorrhagic leuco-encephalitis, where lesions are primarily in the white matter.

(3) Subacute sclerosing encephalitis.

(4) Subacute inclusion-body encephalitis.

To these may be added acute encephalitis due to infection by the herpes simplex virus and those rare cases of encephalitis associated with generalised cytomegalic inclusion disease of children.

Subacute inclusion encephalitis was first described in 1933 when Dawson [2] recorded the case of a 16-year-old boy who died after 7 weeks' illness characterised by involuntary jerking movements and finally by lead-pipe rigidity of the limbs, loss of self-control, and hallucinations. At necropsy eosinophilic inclusion bodies were found in both the nuclei and cytoplasm of degenerate nerve-cells and astrocytes in areas of the brain showing the usual histological picture of encephalitis. He called the disease "inclusion encephalitis" and suggested that a virus was responsible, though none could be isolated. So far 16 similar cases have been recorded, 9 of them in this country [3] [4]; and from them a clinical pattern can be made out. All the patients were between the ages of 4 and 17, and only 2 were over 11. The majority of fatal cases ran a course of from 3 to 9 months, although some survived for as long as 21 months. Brain et al.,[3] who described the first 4 cases in this country, emphasised that the disease got steadily worse over a number of weeks. Psychological changes were usually the first to be noted; deterioration of school work, apathy, forgetfulness, lack of emotion, indifference, and intellectual impairment were commonly found in the early stages. Less often the children showed from the start more definite signs, such as muscular twitching, limping, or a tendency to stumble. Sooner or later, persistent or intermittent muscular spasms appeared, and progressive paralysis followed, leading to severe quadriplegia associated with complete dementia and cachexia. The cerebrospinal fluid either remained normal throughout or showed a Lange reaction of paretic type. Campbell et al.[4] consider that the clinical picture is so striking that it is unlikely to have been missed by neurologists in the past, and they therefore believe that it represents a new clinical entity. They observed 2 children who had the clinical features of subacute encephalitis but who later recovered, and they believe that, as the condition becomes more widely recognised, the prognosis may prove to be more hopeful.

The inclusion bodies accompanying the inflammatory changes in the brain are commonest in nerve-cells, although neuroglial cells may be affected to a less degree. Intranuclear inclusions are usually single and large, and stain with eosin and phloxine; they often fill the nucleus leaving only a few granules of chromatin on the nuclear membrane. The single intranuclear inclusions are probably formed by the coalescence of a number of smaller bodies, for multiple inclusions are sometimes found in the nuclei of less degenerate cells. The cytoplasmic inclusions are multiple, and they are smaller and more strongly eosinophilic than those within the nuclei, but these too may fuse to form a single body sometimes replacing the entire cytoplasm. Ultimately the cell degenerates and shrinks, and is finally represented by a mass of inclusion material. These cells are easily distinguished from the inclusion cells of both herpes-simplex encephalitis and cytomegalic inclusion disease.

Perivascular infiltration with inflammatory cells and gliosis are widespread in the grey matter of the cerebral cortex, basal ganglia, and brain-stem, and may even extend into the dorsal and ventral horns of the cervical cord. The changes in the white matter seem to be secondary to damage to the nerve-cells or to local extension of the inflammation into the subcortical tissue. Virological examinations have been performed in 8 cases, but no virus has yet been isolated. The same applies to cytomegalic inclusion disease, which is almost certainly due to a species-specific virus; and it is probable that the virus responsible for subacute inclusion encephalitis is pathogenic to man only.

A condition with the same clinical picture as that found in subacute inclusion encephalitis was described in 1945 by van Bogaert.[5] In both his cases the brain showed extensive focal inflammation affecting the grey and white matter at least equally. There was partial demyelination, diffuse infiltration with plasma cells, scattered fat-granule cells, and mobilisation of microglia. The most conspicuous feature was a disproportionate neuroglial proliferation in the white matter and in the cerebral cortex. There was less evidence of damage to nerve-cells than in subacute inclusion encephalitis, and no cells containing inclusion bodies were seen. van Bogaert called the condition "subacute sclerosing leuco-encephalitis." Although Brain and his colleagues considered that this leuco-encephalitis was distinct from Dawson's encephalitis, Greenfield pointed out that the two diseases differ only in degree, and that the more thoroughly the brain is examined the more cases of subacute encephalitis will prove to be of inclusion type.

Sir HOLBURT WARING, consulting surgeon to St. Bartholomew's Hospital, and formerly president of the Royal College of Surgeons and vice-chancellor of the University of London, died on Feb. 10, at the age of 86.

no easy matter in a packed day A minute or so before I am due, I cross the frontier and advance briskly down the long corridor In the distance I can see two sisters standing at attention in the open doorway I bow to each, the sisters about turn, I take my place between them, and the three of us march in step along the deserted labyrinth At the bedside we converse for the first—and last—time, finally agreeing on the most appropriate number of aspirins The procession re-forms and the sisters see me to the door, once more standing at attention until I am safely outside the three-mile limit

This ritual, so orderly and dignified, needs only a few touches to rival more famous ones, such as the ceremony of the keys or the admission of a bishop to his cathedral With these in mind, I have proposed certain amendments to the management committee According to my suggested protocol, the physician wears the scarlet gown of a doctor of medicine Three smart taps with a wooden stethoscope on the home door initiate the following dialogue "Who knocks there?" "The doctor" "Whose doctor?" "The nurses' doctor" "Come in, doctor!" The doctor raises his velvet hat thrice, the sisters curtseying each time in reply To round things off, the patient makes a show of resistance (as well she might) when the procession enters her room These proposals incorporate all that is best in our public life, and with the committee's approval I shall seek a *fiat* from the Court of Claims After all, everything has to begin some time, and the sooner this does the better

* * *

H M C Secretary answering a question about a proposed new nurses' home "The committee will be glad to know that the nurses' home at hospital is in the pipe-line at the Regional Board"

* * *

Sometimes we wonder whether the good old days of the last century were a better proposition than the days of 1953 and whether we really work as hard today as did our forefathers I thought I did and expected at least a modicum of sympathy when I remarked last evening in what I hoped was a casual tone that 20 to 30 visits a day did seem a trifle much even for January But my elderly uncle's reply rather shook me He had often wondered, he said, what I considered a heavy visiting-list 70 or 80 used to be his quota for a day and sometimes it was up to 100 And he examined his cases But of course when he was a G P doctors started their visits before breakfast, going on steadily (stopping, I suppose, though he did not mention it, for meals, surgeries, and such-like luxuries) till nightfall Truly those giants of yesterday were tougher than the puny medicos of today But, if he is right, the N H S patient of today is better trained than his grandfather When I put up my feet and relax at what I hope is the end of a busy day I can thank God and the health service that I haven't 70 to 80 patients still awaiting my arrival Perhaps that thought will help me when I am wakened at 3 A M by the phone to hear an old body telling me that her bed is full of ants and will the doctor do something about it But somehow I don't think it will

* * *

MRS BUNDLE

You felt you'd like an overhaul
Rather than trouble me to call
You'd come to me instead
When half way here you wondered ought
You ever to have come and thought
Of going back to bed.

But, though it might be tempting fate,
You struggled on and got here (late)
And talked an awful lot
You never dreamt that I would ask
You to undress—an endless task—
You like to wrap up hot

What you had doffed you had to don
I found with half my morning gone—
Precisely nothing wrong
When next you need an overhaul
Please stay in bed and let me call—
It won't take half so long

Letters to the Editor

REGISTRATION OF FEVER NURSES

SIR,—As an administrator and clinician connected with an isolation hospital which since 1938 has enjoyed the approval of the General Nursing Council as a training school for fever nurses, I should like to draw attention to the recent regrettable decision by that body t enforce, as soon as possible, the ban on the training o student nurses for the Fever Register

The requirement of the General Nursing Council in respect of hospitals to be approved as training schools for nurses was originally a minimum of 100 beds, but this standard was raised in 1947 to a minimum daily average occupation of 100 beds, except in fever hospitals where it was found that owing to the decline in the number of cases of infectious disease the requirement could not everywhere be implemented In 1949 the General Nursing Council first expressed the wish that entries to training for admission to the Register for Fever Nurses should cease as soon as possible, although no inquiries were then made regarding those fever hospitals which could attain the required minimum daily occupation of 100 beds

In the particular hospital with which I am associated the daily average occupation of beds has risen from 66 in 1938 to 112 in 1952 and the total annual admissions from 700 to 1264 Yet the management committee has been informed that student nurses must not be accepted after the end of 1953, and that training of student nurses for the Fever Register must be terminated four years thereafter As far as I am aware, the General Nursing Council has taken this final step without consulting those concerned in the fever hospitals recognised as training schools, and apparently without a sense of the irreparable harm which might be done to the nursing and hospital services of the country It has been suggested that the nursing experience available in infectious-disease hospitals should be used to enrich the training of student nurses from general hospitals In the hospital group to which I am attached this has been the practice for two years, the student nurse serving for one period of three months in the infectious disease wards as part of their general training, but in no way can this be considered equivalent to the longer training of the fever nurse It has only been possible to carry on the fever hospital by having a large staff of student nurses in training for the Fever Register, and the staffing problem of the isolation hospital cannot be solved by this short period of fever nursing included in the general training of nurses The position might be easier if the General Nursing Council were to decide that fever training should be a compulsory component of the syllabus of training for general nursing, but this decision is not likely to be made There is no suggestion that fever training and registration might continue as a postgraduate accomplishment of the general trained nurse—a course which might also help to solve the problem, and would be much more acceptable and fruitful than the suggested inclusion of fever nursing in a scheme of training for assistant nurses

This attitude to the training of students in a branch of nursing which has a technique all its own would imply that there is something inferior in the fever trained nurse In the opinion of many clinicians and hospital matrons the fever trained nurse is a highly valued member of the profession Fever training i essential for the ward sister in charge of a ward for infectious diseases and for the senior nursing staff of an infectious disease hospital It is an extremely valuable asset to sisters in charge of tuberculosis and children's wards, and it should be essential for the health visitor engaged in making epidemiological inquiries and giving in Greater London that there was an appreciable increase in mortality in the week ended Dec. 13. In the remainder of the great towns (aggregate population 14 million) the increase amounted to only 164 deaths, compared with an increase of 2641 in Greater London. Incidentally the fact that the subsequent rise in numbers of registrations in the weeks ended Jan. 3 and 10, already noted for Greater London, was paralleled in the remainder of the great towns supports the suggestion that this later increase in mortality was independent of the fog.

Within the Greater London area the abrupt increase for the week ended Dec. 13 occurred both in the central area (administrative county) and in the outer ring; as the right-hand column of table II shows, the weekly mortality in the central area almost trebled (ratio 2·6) and in the outer ring it doubled (ratio 2·0). The breakdown of the outer ring into towns within the constituent county areas indicates that mortality increased most sharply in the Essex section (ratio 2·5) and least in Kent (ratio 1·7). But clearly no large section of the Greater London area escaped. As examples of what happened in some districts, deaths registered in Stepney increased from 29 to 119 (ratio 4·1), and in East Ham from 16 to 62 (ratio 3·9).

TABLE V—NUMBERS OF DEATHS ASSIGNED TO VARIOUS CAUSES, LONDON ADMINISTRATIVE COUNTY: WEEKS ENDED NOV. 29, 1952, TO JAN. 3, 1953

Cause of death	Week ended Nov. 29	Dec. 6	Dec. 13	Dec. 20	Dec. 27	Jan. 3
Respiratory tuberculosis ..	19	14	77	37	21	24
Cancer of lung ..	27	45	69	32	36	48
Vascular lesions of C.N.S. ..	98	102	128	119	91	131
Coronary disease ..	131	118	281	152	109	150
Myocardial degeneration ..	79	88	244	131	108	136

Other respiratory diseases ..	8	9	52	21	13	10
Motor-vehicle accidents ..	1	8	4	10	4	5
Suicide	5	10	10	7	5	12
Total (all causes)	853	945	2484	1523	1029	1372

* Excluding deaths at ages under 4 weeks.

ANALYSIS OF DEATHS

Age-distribution

Table III compares the age-distribution of deaths registered in the London administrative county in the weeks ended Dec. 6 and 13. Although the increase in mortality was greater at older than at younger ages it was slightly less at ages 75 and over (ratio 2·7) than at ages 45–74 (ratio 2·8). The mortality of newborn infants almost doubled, and that of infants aged 1–12 months more than doubled. Deaths of children rose by a third (from 10 to 13) and of young adults by close on two-thirds (from 61 to 99). It is clear, therefore, that all ages shared to some extent in the increased mortality, and that it was by no means confined to the very young or the very old. Altogether there was relatively little disturbance of the usual age-distribution of deaths, as is shown in table IV which gives the percentage of deaths at various ages during several successive weeks.

TABLE VI—DEATHS FROM BRONCHITIS AND FROM PNEUMONIA BY AGE, LONDON ADMINISTRATIVE COUNTY: WEEKS ENDED DEC. 6, 13, AND 20, 1952

Age (years)	Bronchitis			Pneumonia (at ages over 4 weeks)		
	Dec. 6	Dec. 13	Dec. 20	Dec. 6	Dec. 13	Dec. 20
Under 1 ..	2	6	1	5	9	7
1–44	—	11	4	2	4	6
45–64	21	193	95	11	31	16
65 and over ..	53	494	296	27	124	96
All ages ..	76	704	396	45	168	125

Causes of Deaths

Deaths registered in the London administrative county increased by about 1500 in the week ended Dec. 13, and the about half of the increase was attributed to bronchitis or pneumonia. Deaths from bronchitis increased by over eight times (from 76 to 704) and deaths from pneumonia by almost three times (from 45 to 168) (table V). In the next week—the week ended Dec. 20—deaths from bronchitis totalled 396, still a very high figure, and deaths from pneumonia numbered 125. Other causes of death that increased greatly in the week ended Dec. 13 were respiratory tuberculosis (from 14 to 77), cancer of lung (from 45 to 69), coronary disease (from 118 to 281), myocardial degeneration (from 88 to 244), and "other respiratory diseases" (from 9 to 52). 24 deaths were certified as due to influenza compared with 2 in the previous week. There was no increase in deaths from motor-vehicle accidents—possibly because fewer vehicles were on the roads—and there was no increase in deaths by suicide.

The age-distribution of deaths from bronchitis and from pneumonia are shown in table VI. As for deaths from all causes combined, the increases were greatest at advanced ages, but young persons by no means escaped. Deaths from bronchitis at ages under 45 rose from 2 in the week ended Dec. 6 to 17 in the next week, and deaths from pneumonia almost doubled (from 7 to 13).

TABLE VII—NUMBERS OF DEATHS CERTIFIED BY CORONER OR CERTIFIED AFTER POST-MORTEM EXAMINATION, GREATER LONDON: WEEKS ENDED DEC. 6, 13, AND 20, 1952

Week ended	Total deaths	No. certified by coroner	No. certified after post-mortem examination		
			Coroners'	Others	Total
Dec. 6 ..	2062	458 (*22%*)	452	169	621 (*30%*)
Dec. 13 ..	4703	962 (*20%*)	960	267	1227 (*26%*)
Dec. 20 ..	3138	680 (*22%*)	680	203	883 (*28%*)

Deaths Certified by Coroners

One of the results of the sudden increase in mortality was to double the work of coroners and coroners' pathologists. Their reports will provide valuable information about the pathological changes found and may throw

TABLE VIII—DEATHS IN GREATER LONDON AND CONSTITUENT AREAS BY DATE OF OCCURRENCE, DEC. 1–15, 1952 (EXCLUDING ANY DEATHS OCCURRING WITHIN THESE DATES BUT NOT REGISTERED BY DEC. 20). ATMOSPHERIC POLLUTION READINGS AT KEW OBSERVATORY, RICHMOND (SOUTH-WEST LONDON)

5 *Disorders of muscular rhythm and of gait, and trick movements* are related to the defects of muscle power, over action of antagonists, myogenic contractures, and the influence of extrinsic forces, including gravity and peripheral fixation of limbs The variations in muscular torque in response to gravity, acceleration, and deceleration, the association of the paradoxical effects of peripheral fixations, and synergic inhibitions—these together form a problem of the utmost complexity in the diffuse and often incomplete palsies of poliomyelitis

There are other function structure derangements

(a) *Pseudo arthritis*, as described by Poynton and others

(b) *Vascular disorders* of whole regions, which are well known to contribute to limb shortening and defects in skin, and which presumably contribute to the muscular defects already noted

(c) The combined effect of *extrinsic forces and intrinsic defects*, causing secondary distortions in bone and derangements of articular tissues

These problems do need further study, but special poliomyelitis centres are not required Cooperation by teams including a physiologist, neurologist, physiotherapist, and nurse with the orthopædic surgeon in existing orthopædic centres is the ideal approach, which could be readily achieved

Exeter NORMAN CAPENER

MORE FOOD

SIR,—In his letter (Jan 24) Dr Bender says that he finds it difficult to imagine any reward sufficient to attract a farmer to marginal land But I know a hard-working farmer for whom there is more than one a marginal farm can be made to pay financially (though it may not be easy), but far more rewarding is seeing the improvement in land, crops, and head of stock which can be carried, and hearing neighbours and visitors remark on this improvement Oil lamps are still used, but the enjoyment and satisfaction of doing a worthwhile task well is, in this case at least, a great part of the reward, and the amenities of a civilised life are not necessarily those found in cities

Edinburgh J A WATT.

ŒSOPHAGEAL CONTRACTION AND CARDIAC PAIN

SIR,—Your issue of Dec 6 contained the St Cyres lecture delivered by Dr William Evans a few months previously

Having attended his lecture and disagreed profoundly with his statements, I have since carried out investigations into the frequency of reflux of barium within the œsophagus, as my own conviction was that this was not pathological and was, in fact, common

The first three young subjects examined at a barium-meal session showed reflux within the œsophagus, this appears to occur when the diaphragm in inspiration occludes the lower end of the œsophagus, and when that occlusion is more powerful than œsophageal peristalsis The reflux, in fact, occurs by relaxation of the œsophagus, and there is never at any time any suggestion of retrograde peristalsis

In the course of an investigation being carried out to elucidate the earliest signs of hiatus hernia, the "œsophageal arrhythmia" described by Dr Evans has been observed in a very large number of patients, it seems to take place in at least 50% of normal subjects There can be no doubt that this feature is entirely physiological and in no instance so far encountered has it been associated with "cardiac like" pain

The reflux is found most usually in patients with a demonstrable phrenic ampulla, and this latter appearance seems also to be related to the efficiency with which the diaphragm occludes the lower end of the œsophagus

R A KEMP HARPER

PRACTICAL PENICILLIN

SIR,—As one of the general practitioners in whose practice Mr Cohen carried out part of his investigations, I was interested to read his report (Jan 24) and the letter from Dr Ryle (Jan 31)

The regimen introduced by Mr Cohen has been continued here in this practice, and my partners and I can vouch for the efficacy of a large single dose of 'Distaquaine Suspension' in many of the cases of sep encountered in our daily work In addition, there is no doubt that this method simplifies treatment and saves time and trouble to our patients and to us

Mr Cohen is obviously the best man to reply to Dr Ryle's several points, and I have no doubt that he will, but as he is now permanently resident in Suva Fiji, there will probably be some delay

Liverpool J SITNER

BOVINE TUBERCULOSIS AND HUMAN TUBERCULOSIS

SIR,—Dr Bradshaw (Jan 31) refers to the mistakes in my figures (which have been corrected), and says that they call in question the accuracy of the remaining data I should like to say that a copy of the *Veterinary Record* which contained these data was sent on Aug 17, 1951 to each of the medical officers of health who had supplied me with figures, none of them reported any inaccuracy or disagreed with my deductions I hope that medical officers who have followed this correspondence will say so if I am wrong

Dr Bradshaw says that "immunity to tuberculosis can be produced by certain types of living mycobacterium" Will he give me evidence of this and explain why it is not generally applied? He adds "dead organisms or bacterial products have never been shown to produce immunity" What does he think about London, where practically all of the milk is heat treated and comes mainly from non designated sources and where, on the whole, tuberculosis is much less serious a problem than it is in the counties of Scotland with a very high proportion of cattle attested?

Dr Anderson (Feb 7) says that I have made "the mistake of estimating the incidence of pulmonary tuberculosis from notifications statistics"

I have said that the eradication of tuberculosis from cattle leads to an increase in pulmonary tuberculosis in human beings for, taking Scotland as a pattern, out of 11 counties with a high proportion of cattle free from tuberculosis, 10 show such an increase—some a very big increase Out of 11 counties with few uninfected cattle, 10 show a very considerable reduction in human notifications This broad average seems to confirm my view

Dr Anderson mentions county health authorities as advising attestation of dairy herds I think he is confusing "attested" with "tuberculin tested," for local authorities play no part in the formation of attested herds The granting of a "tuberculin tested" licence is certainly the province of the local authority, but an "attested herd" certificate is granted by the Ministry of Agriculture An attested herd is a herd in which all the animals have given a negative result to 3 consecutive tuberculin tests After 1954, only milk from attested cattle may be designated as tuberculin tested

Turning to "the uncertain remote benefits of drinking tuberculous milk," tuberculosis of the udder, and so of the milk, is an extremely rare condition in cows By contrast, the milk of cattle free from tuberculosis contains none of the antibody substance, and the drinking of it makes human beings highly susceptible to the human bacillus and to pulmonary tuberculosis Incidentally, non pulmonary tuberculosis is commoner in English counties with a high proportion of attested cattle Finally, the risk of a milk borne infection (which can be eliminated by heat treatment) is much less than that of a certain increase in notifications of pulmonary disease where the cattle are free from tuberculosis

High Wycombe L PITCHFF

nd interference with, water-supplies: a limited mains pply of chlorinated water has been provided for mestic and washing use and a ration of about a gallon pure water a day a head brought into the island for inking and cooking purposes. Elsewhere there has en little or no interference with main water-supplies, ough many have been chlorinated as a precaution, it surface wells have been affected by flooded sewers nd people have been advised locally to boil all water. s most of the flood water is brackish, contaminated pplies are usually unpalatable.

At Kings Lynn the Isolation Hospital was flooded, nd evacuated just in time. The other hospitals in the wn were affected, but were able to keep going. Except r the railway Tilbury Hospital has been completely olated by the floods; but it has not been evacuated nd has continued to serve the population round the ocks. Long Reach Hospital, Dartford, was flooded; is the main smallpox hospital for the London area nd was empty: alternative arrangements have been ade to deal with any cases that might arise. Two onvalescent homes and one small hospital in other gions were put out of action. Otherwise the hospitals caped lightly and could deal with the patients brought them suffering from injury, shock, or exposure, as ell as a number of old people normally cared for at ome but too frail for rest centres. Arrangements were de for transfer of casualties to other hospitals inland necessary, but happily little use had to be made of is precaution.

Local general practitioners worked hard and well to aintain services, and many offers of help were received om other areas. Instructions have been given to those oncerned that spectacles and dentures lost or damaged n the disaster are to be replaced as speedily as possible, ee of charge.

The great problem, however, has been a welfare one —the care of the homeless. Rest centres were opened n all the affected areas and many thousands passed hrough them. Voluntary workers and officials have ombined to smooth out the immense difficulties of handling such great numbers of cold, wet, frightened people, of warming, feeding, and identifying them, and f passing them on to friends, relations, or voluntary billets. Known cases of open tuberculosis have been taken out of the rest centres and admitted to sanatoria. The central reserve stores have contributed blankets, mattresses, camp-beds, heating stoves, crockery, towels, nappies, and all the many things needed over and above the great stream of clothing which is flowing so swiftly and steadily from all parts of the country.

At the time of writing, a week after the disaster, the [illegible] changing. Most of the homeless have [illegible] but in certain areas there is still a sub- [illegible] number awaiting accommodation. The flood waters are receding and the problem of cleansing houses of mud, often sewage-contaminated, has to be faced. There is no reason at present to fear an outbreak of enteric, but the possibility of odd cases, even of small outbreaks, of this or other sewage-borne infections cannot be entirely excluded in areas where contamination with sewage has occurred. Meanwhile influenza is complicating some of the work but not so far seriously. The critical emergency is over for the moment (though another high tide is due at the end of this week) and those concerned are looking forward to the long and difficult task of restoring normality.

Statistics for 1921–30

Part III[1] of the Registrar-General's Decennial Supplement series for 1931 has now been issued. This volume groups the data for England and Wales on population, births, marriages, and deaths previously published in the annual statistical reviews for the ten years 1921–30.

---

[1] Registrar-General's Decennial Supplement, 1931, Part III. H.M. Stationery Office. Pp. 574. £3 10s.

Influenza

The indications, reported last week, of an increased incidence of influenza in London and Southern England have been followed by a distinct increase in the number of deaths from this cause. In the 160 great towns such deaths totalled 313 in the week ended Jan. 31, compared with 29, 51, 72, and 132 in the four preceding weeks from Jan. 3 to 24. In London and the south eastern region there were 219 deaths, while in Greater London alone there were 170 deaths. Elsewhere, only in East Anglia has there been any considerable relative increase in deaths—to 25 in the week ended Jan. 31, compared with 3 in the previous week. Other regions of England and Wales remain free from any widespread outbreak of the disease.

In the week ended Jan. 31 the 313 deaths in the great towns were distributed by age as follows: under 1 year, 1; 1–5, 3; 5–15, 1; 15–25, 3; 25–35, 4; 35–45, 9; 45–55, 9; 55–65, 46; 65–75, 104; 75 and over, 133.

Laboratory reports confirm that the majority of the cases are due to the "Scandinavian" strain of A-prime virus, though virus B has been reported to be present in certain areas.

Emergency Bed Service.—A red warning was replaced on Feb. 3 by a yellow warning, which was withdrawn on Feb. 4 but reimposed on Feb. 10.

Weekly Claims to Sickness Benefit.—The weekly claims on the Ministry of National Insurance (including Scotland) for sickness benefit since the start of this year, with comparable figures for 1952, have been as follows:

Week ended	*Claims* *1953*	*1952, corresponding week*
Jan. 6	199,063	188,164
Jan. 13	208,168	166,409
Jan. 20	201,721	155,292
Jan. 27	239,091	162,522
Feb. 3	276,883	175,552

Fluoridation of Water-supplies

Six years ago the civic authorities of Marshall, Texas, agreed to the addition of fluoride to the town's water-supply. It is now reported[1] that six-year-old children in Marshall have less than half the number of dental cavities found in children of the same age living in neighbouring towns. It is said that more than 35% of Marshall children have no dental caries, compared with 13% in nearby Jacksonville.

The Third Quarter in Eire

In Eire during the September quarter of 1952,[2] the birth-rate was 21·5 per 1000 population, and the death-rate 9·9. The death-rate for tuberculosis was 0·4 per 1000 population (respiratory 0·3 and other forms 0·1), compared with 0·6 (0·4 and 0·2) in the corresponding quarter of 1951. The maternal-mortality rate was 1·6 per 1000 births registered (0·9 in the corresponding quarter of 1951). The infant-mortality rate was 36, and the neonatal death-rate 20, per 1000 births registered.

* Not including late returns.

affecting the patients, and (2) the practitioner and the way in which he conducts his work—a personal and individual matter which each G P will work out for himself

"Dr Cort is surprised at the relatively small amount of work which my practice entails In turn I am astounded at the figures which he quotes for his practice In my practice over the past-four years the average attendance rate per patient per year has been 3 5 This compares with figures of 4 1 from a semirural practice,[2] 5 7 from a rural practice,[3] and 5 from the Social Survey unit[4] Prof Bradford Hill[5] also quotes a figure of 5 for National Health Insurance patients in 1938, while the Ministry of Health at an inquiry in 1937 gave a figure of 3 66 Thus the average number of attendances per patient per year seems to be between 4 and 5 Yet Dr Cort, with 30,600 attendances for 2600 patients, gives a yearly attendance rate of 12

"Assuming that Dr Cort works six days a week in a year, it can be seen that he does an average of 40 visits a day and sees some 60 persons in his surgery If he works rapidly, at a rate of five minutes for each surgery consultation and ten minutes for each visit, this volume of work will necessitate some twelve hours' work daily He says that two or three years ago he attended 45% of his entire list (2600 units) in a week This means that in one week he attended to 1170 of his patients at a rate of 167 a day for seven days a week, necessitating some nineteen and a half hours' work a day (excluding meals and other personal essentials)"

An editorial comment will be found on p 332 —Ed L

ACROMEGALY AND NEUROFIBROMATOSIS IN SISTERS

Sir,—The following is a record of two sisters, one of whom suffered from acromegaly and the other from neurofibromatosis (von Recklinghausen's syndrome)

A woman, aged 65, was admitted to Bootle Hospital with symptoms of intestinal obstruction and with dysuria In addition she had advanced acromegaly with prominent jaw, large tongue, big hands and feet, and hirsuties Her general condition was poor and she was emaciated A large mass was detected in the pelvic colon, and there was gross pyuria Other preliminary investigations showed a blood sugar level of 300 mg per 100 ml (but no glycosuria) and a blood non-protein nitrogen level of 36 mg per 100 ml Radiography of one hand showed typical acromegalic changes, but the pituitary fossa was within normal limits

Her sister, aged 61, with whom she lived, was noticed to have extensive neurofibromatosis involving the face, neck, and arms (and probably elsewhere) in association with areas of pigmentation This sister was feeble minded and extremely apprehensive She would not allow detailed clinical examination, and permission to take photographs of either of them was refused

While investigation of the acromegalic sister was proceeding she suddenly vomited, appeared to aspirate most of the vomit, became cyanosed, and died in asphyxia Necropsy showed a large adenocarcinoma of the descending colon, pyelonephritis, and cystic degeneration of the anterior pituitary

The coincidence of acromegaly and neurofibromatosis is well known Sternberg[6] in his early monograph on acromegaly states "Mollusca fibrosa of various sizes especially on the face and eyelids is frequent," and he cites nine reported instances More recently the association of these two disorders has been described by Ormond,[7] de Castro,[8] Barber and Shaw,[9] and others Although in both syndromes a familial tendency is recognised, this is, so far as I can ascertain, the first time that acromegaly and neurofibromatosis have been recorded in siblings

ISOSPORA BELLI (WENYON) FROM DUODENAL INTUBATION

Sir,—Despite the fact that we have encountered numerous cases of coccidiosis in man[1] the site of infection remains unknown The condition seems to be self limiting and has not, in our hands, come to necropsy, so the exact source of the oocysts we observe in the stools remains in doubt

Recently we had a patient with nephritis who was passing in the stool an exceptionally large number of oocysts of *Isospora belli* and had passed a solitary *I hominis*

A duodenal tube was passed on two occasions, and the stomach and duodenal contents submitted to zinc sulphate flotation On the first occasion oocysts of *I belli* were found in both the duodenal juice and the somewhat bile stained gastric contents The tube was passed on a second occasion and this time the first specimen of gastric juice contained no oocysts that we could find The duodenal fluid, and a second suction of gastric contents—this time bile stained—both showed oocysts of *I belli*

The finding of the parasites in duodenal fluid suggests that the site of infection may be the duodenum or bile tract A large proportion of the oocysts seen were in the two sporoblast stage—a fact difficult to reconcile with our usual experience with *I belli* in which, in contradistinction to *I hominis*, the parasites are immature on arrival in the stool There may be some development in the deeper tissues, such as occurs with *I bigemina*

Our thanks are due to Dr J C Thomas, Provincial pathologist, Natal Provincial Administration, for laboratory facilities, and to Dr N R Pooler and Dr A L Brown for access to the case

"GOLF BACK" AND THE NEW SWING

Sir,—Is the modern golf swing liable to produce lame back?

The movement is essentially a long swing with a braced left arm, the left wrist being "locked" by showing three or four knuckles It employs the fullest body shoulder pivot with the trunk held much more erect than in the traditional method, from which, essentially, all wrist-rolling action is deleted

No less an authority than Mr *Henry Cotton* alleges that the new swing contributes to a growing number of players with injured backs,[2] and he regards its teaching as a bad discipline In America, where this technique is most widely used, a number of top ranking professional golfers have been disabled by what is popularly described as "slipped disc," while in this country there have been similar examples of "golf back"—notably the case of Mr Harry Weetman The questions therefore are whether the modern swing is unphysiological, and whether golf back is in fact more prevalent today among those who use it

Having recently acquired this technique at the hand of Mr Max Faulkner, who is perhaps its leading exponent in this country, I regard the movement as no more and no less unnatural than the traditional swing And I think we should be very cautious about accepting the contention that it is more liable to cause disability Lame back has always been recognised as an affliction of golfers, though usually a transitory one And while the nature of this disability has defied precise analysis it is probably fair to say that the popular notion that most examples are due to "discs" is incorrect Any golfer in middle life (or for that matter any athlete of like age) who suddenly changes the execution of a luck, she may not. But at all events the state of the child's emotions has been recognised as an essential factor in education: the intelligence cannot function rightly unless all is well with the feelings. Every gain in knowledge and skill is steadying and releasing, enabling the child to go on towards maturity. In addition to his bread-and-butter tasks the child needs as she put it, experience of pungency and excellence. Nothing but commonplace experiences makes a commonplace person. The right kind of books should fall in his way at the right time. She mentioned *The Kon-Tiki Expedition* and *The Worst Journey in the World* as offering pungency; and any subject can give the child experience of excellence. The woodwork master and the games master share a particular claim to success here because they can demonstrate skill. The child under eight needs the opportunity to enter into group projects; but he expects a school to be a school and not a child-guidance clinic, and within those limits should be able, she said, to get the emotional nurturing he needs from the teacher. Round about eight he reaches a crisis in which the need to excel in some direction or another is very strong, and the success of others can produce a sense of inferiority. The character of the emotional nurture provided by the teacher should change from mothering to friendliness and interest, and the group projects should have more objective and real ends. Aggression needs some outlets other than surreptitious sulks, or semi-hysterical laughter at the unexpected gift of a joke from the rostrum. Even an explosion from the teacher, used skilfully, has its advantages. Adolescents need individual contact and respond well to the tutorial system; a transference situation is almost necessary for successful teaching at this age, and it is the experience of universities that an undergraduate may discover it was the schoolmaster, not the subject, that he liked. The sullen wooden school-child who is unable to learn often speaks of the teacher as "she," and the rest of the class as "they," because he feels out of it. Affection and interest may decide whether he is able to keep going or not. How much of all this can be got across to the ordinary teacher? Directly, Miss Bartlett thought, relatively little; indirectly much. A course of lectures on the backward child will attract every teacher within reach, whereas one with the same content but entitled "Mental Health" will hardly bring in one.

[1] Elsdon Dew R Freedman L S Afr J clin Sci 1950 1 182 Elsdon Dew R Freedman L Trans R Soc trop Med Hyg (in the press)
[2] *News of the World* Dec 7, 1952

In the ensuing discussion a school-teacher urged that the principles of mental hygiene should be taught to girls in secondary schools, since they would be having to put them into practice on their own children in a few years' time. Another speaker defended the day-nurseries, which she said often prevented children coming into care by giving the harassed mother just the relief she needed, and by providing for the child what was in essence an extension of the home.

Recent Research into Mental Illness

At another session, Dr. DENIS HILL (physician for psychological medicine, King's College Hospital) said the factors which may prevent an individual from adapting himself to his environment are constitutional and environmental, and the interplay between them. The danger-signal is anxiety. In the infant emotional development is hindered when normal gratification is reduced (for instance, by separation from the mother); or rationed (by a too strict feeding régime, or other evidence of hostility); or impossible (perhaps because the father is too powerful a rival). Psycho-analytic theory has not shown why one person responds to stress by neurosis and another does not; but differences of genetic endowment must play some part. Studies of twins have shown that there is a single-factor type of inheritance for schizophrenia. If one of a pair of identical twins has schizophrenia there is an 86% chance that the other will develop it. With ordinary brothers and sisters and non-identical twins the chance is only 14%, and in half-brothers only 7%. Conditions reducing the stability of the body-weight reduce the resistance to schizophrenia in those predisposed to it. There is also evidence that a tendency to neurosis is inherited, but here multiple genes are involved. Stresses and resistances vary: thus one form of stress may break down a weak resistance in a person vulnerable to almost any stress; but may also find the Achilles heel in a person who would resist other kinds of stress. Some physical evidence of liability to schizophrenia may be offered by the type of skin capillary loops visible in the nailbeds. Possibly in this disease these are immature in type, and it may become possible to think in terms of capillary age much as we think in terms of bone age. Modern techniques, such as the use of the electro-encephalograph, the electron microscope, the behaviour of radioactive substances in the brain, the response to anoxia, glucose starvation, and various drugs, are beginning to provide us with new evidence. It has been shown that schizophrenic patients are unable to maintain a constant level in almost all physiological functions. The adrenal cortex pours over 90 secretions into the blood; and in America the adrenal cortex has been removed in some cases, and substitution therapy given. The results cannot yet be assessed. Many epileptics have a hyperexcitable area in the temporal lobes; in some cases this can be removed surgically, with benefit to the patient. Electrical stimulation of small areas of the temporal cortex, during the operation, has caused these patients to recall vividly some event or events in their past lives—so vividly that as far as they are concerned they relive the scenes. Yet when these areas are removed they can still recall these events, and can remember that the surgeon was able to stimulate recall in this way.

Dr. R. STRÖM-OLSEN (physician-superintendent of Runwell Hospital), speaking of the influence of recent advances in the prevention and treatment of mental illness, remarked that there is as yet no agreement on standards of mental normality. He reviewed briefly the many methods of prevention and treatment now in use. Child guidance, he said, is reducing the incidence of adult neurosis, Darby and Joan clubs are reducing the danger of mental breakdown in old age, and youth clubs, vocational guidance, and marriage guidance are all useful forms of preventive work. We have a growing knowledge of the effect of drugs for narcosis, for abreaction, and in neurophysiological research. The multidimensional approach in neurosis is giving results, and day hospitals, and psychiatric social clubs are valuable in the treatment of patients getting back to work, or suffering from the loneliness so common among the mentally sick. These are the more valuable in that long inpatient treatment of neurotics has never been very successful. Psychodrama, drawing, painting, and sculpture are also proving effective means of expression. In America they have tried putting two psychiatrists, one more senior, on to the same case; they treat him jointly, and it is said that the transference is more easily dissolved in these circumstances. Outpatient methods are developing. Disulfiram ('Antabus') has provided a new and successful means of dealing with those alcoholics who will tolerate the treatment. Œstrogen therapy has been of great service in reducing hypersexuality in males, and in particular has given relief to homosexuals. The value of male sex hormone in the treatment of frigidity in women has not yet been substantiated. In the field of neurosurgery the standard prefrontal leucotomy operation has given place to open operation and the more exact techniques of topectomy and cortical undercutting, but no final opinion on results can be given as yet.

tuberculosis, and the steps taken to combat that disease had frequently been described With the greatly reduced tuberculosis mortality in 1951, the latest year for which detailed figures were available, the female death rate fell below the male rate

Replying to further questions, Commander Galbraith said the death rate from respiratory tuberculosis among women between 15 and 35 years of age in Scotland had fallen from 149 per 100,000 in 1948 to 56 in 1951 The corresponding rates for England and Wales were 68 and 28 The precise reasons for the continuing disparity between the two countries were not known, but he saw no reason why the measures taken in recent years to combat the disease should not result in this disparity being further reduced in the near future

Mental Hospitals' Staff

Replying to a question, Miss M P Hornsby Smith stated that the deficiency of nursing staff in mental hospitals was now about 3500 men and 7600 women In 1947, the first year for which figures are available, the deficiency was 2300 men and 7000 women The numbers employed had increased since 1947 by 1200 men and 3800 women (counting part timers as a half), but the needs had increased at a greater rate

Registration of Opticians

Replying to a question, Mr Iain Macleod said that in conjunction with the Secretary of State for Scotland he proposed discussing the findings of the Interdepartmental Committee on the Statutory Registration of Opticians with the bodies concerned, with a view to preparing proposals to be laid in due course before the House of Commons It should not be inferred that the Government accepted all the detailed recommendations of the committee

Atmospheric Pollution

Replying to Mr. Somerville Hastings, Mr Harold Macmillan said that as far as was known there was no reduction in the amount of sulphur dioxide emitted to the atmosphere when coal and coal products were burnt in slow combustion stoves, but probably a little less smoke was formed from coal

Obituary

ALAN STUART WHITEHEAD

M D , M Rad Lpool, D M R D

Dr A S Whitehead, consultant radiologist to the Eastern Hospital management group of the Liverpool Regional Hospital Board, died on Feb 2 at the age of 36

He was educated at King George V School, Southport, and the University of Liverpool, where he graduated M B in 1941 and was awarded the clinical exhibition in medicine He acted as house-surgeon and house-physician at the Emergency Hospital, Southport, during 1941–42 and later he served in the R A M C He spent a short time in general practice before taking the postgraduate course in radiology at the University of Liverpool in 1947 In 1948 he was appointed registrar in the Royal Liverpool United Hospitals and later senior registrar at Broadgreen General Hospital and Mill Road Maternity Hospital In 1949 he took the D M R D and the M RAD Two years later he became assistant radiologist to the Eastern Hospital group and last October consultant radiologist to Mill Road Maternity Hospital Newsham Hospital and Bootle General Hospital He graduated M D last year His published work included papers on Congenital Toxoplasmosis, Radiological Double Contour Effect, and Placentography

P H W writes "Whitehead's advice was continually sought by his colleagues and they thought highly of his opinions which were so willingly given Since his work was of such a specialised nature we invited him to help us with the postgraduate course in radiology he freely gave his time to the teaching of the students and we could always rely on him to help with additional work He will be greatly missed by all his colleagues in hospital and by the students It is tragic that so young a life should be cut short at the beginning of a promising career"

Dr Whitehead leaves a widow and two children

EDWARD EDMONDSON PAGET-TOMLINSON

M D Camb

Dr Paget-Tomlinson, who died at Ulverston, Lancs on Jan 20, at the age of 70, came of a Westmorland family He was the son of W S Paget Tomlinson F R C P , who had retired from his Liverpool practice in 1890 on succeeding to the Tomlinson estates at Kirkby Lonsdale

Edward Paget-Tomlinson qualified from the London Hospital in 1909, and after holding house appointments there he took his M B Camb the following year Fo some time he practised at Malton, Yorks, later moving to Horncastle, Lincs, where he was appointed surgeon to the Horncastle War Memorial Hospital He was also in practice for some years at Kirkby Lonsdale before he retired to Ulverston During the late war he interrupted his retirement to act as medical officer to the A R P service there, and he was a willing and valuable temporary helper in any local war-time emergency

P M -B writes "P -T , as he was popularly called in my early days at the London Hospital, represented the type of sportsman who sprang from Cambridge University—beautifully proportioned, clean in mind and clean in body, and an adept at every form of field athletics, excelling especially in the jumps and hurdles, but he was as keen on his work as on games To him life was a series of grand and exciting experiences, for he delighted in all forms of plant and animal life The picture of his cheerful, handsome face and his sincere manner has always remained with me Equally charming and considerate to everyone in all walks of life, it is small wonder that his name became a household word wherever he practised"

JOSIAH OLDFIELD

M A , D C L Oxfd, M R C S

Dr Oldfield, who died on Feb 2 within a fortnight of his 90th birthday, brought into our own times the breadth and liveliness of interest of a Victorian amateur of reform

He was born at Shrewsbury, the son of David Oldfield and educated at Newport, Salop, Grammar School and Oxford University, where he took a second class in the honours schools of theology and law Called to the bar at Lincoln's Inn in 1892, he practised in the Oxford circuit before beginning to study medicine at St Bartholomew's Hospital, where he qualified in 1897 Shortly afterwards he founded, in the New Kent Road, the Humanitarian Hospital of St Francis, of which he was for some time chairman and senior physician

But medicine remained only one of his interest In 1901 he was awarded the D C L of Oxford University for his thesis on capital punishment, and in the same year he founded the Society for the Abolition of Capital Punishment Though many thought his interests as a reformer were too diffuse, he went to great pains to collect first-hand information about the reforms he advocated and in the winter of 1901 he visited India to study, in his own words, "the effect of the English Government on the people," and to try to discover "the reality of their grievances and at the same time to learn the cause of the modified success of the Christian Missions" there

He had been partly drawn to medicine by his interest in dietetics, and in 1903 he became warden and senior physician to the Lady Margaret Fruitarian Hospital at Sittingbourne, Kent He also practised as a consultant in digestive diseases He had himself adopted the fruitarian diet while at Oxford and he strenuously advocated its adoption "by the higher classes for æsthetic and humane reasons" He supported his theories by the practical method of planting fruit trees and by writing many popular books, including *Diet in Rheumatism*, *Diet in Digestion*, *Fasting for Health and Life*, and *Eat and Keep Well*, and he wrote many vigorous letters to the newspapers

During the 1914–18 war he raised and commanded a field ambulance, and he held the rank of lieut -colonel in the R A M C Soon after the war he continued the study of the effect of British government on subject peoples, which he had begun in India, by a tour of the West Indies, and during this visit he was admitted to the Jamaican Bar revolutionary change in our moral outlook, violence would become our master.

The meeting passed unanimously a resolution calling on the Government to reject the proposed Bill.

Medicine and the Law

The Nurse and the Tea-tray

After the perils of hot-water bottles in hospitals and nursing-homes[1] we have now the perils of the hot-water jug on the tea-tray. In Trew *v.* Middlesex Hospital[2] it appeared that a nurse placed a tea-tray on the lap of a private patient sitting up in bed. The tray tilted and hot water from the jug was spilt and burnt him. The plaintiff's allegations of negligence were that the hospital ought to have provided a bed-table, or that the nurse should have set the tray in a safe position or should have ensured that he had control of it. The patient had one leg in a sling and the other on a pillow; he had been sitting as upright as he comfortably could. There was perhaps not much room on the bed for a horizontal position for the tray. The evidence of the nurse was that the patient was somewhat impatient; she said she had asked him if the tray was all right and he had assured her it was. The defence also emphasised that the patient had immediately received an apology and had said "Accidents will happen." It was suggested, moreover, that the injury was not very serious.

Mr. Justice Gerrard said that the nurse was a small, brisk woman who, according to the plaintiff, was in a hurry. Generalising perhaps a little speculatively, he said he could well imagine, and he thought it was a fact, that the nurse "breezed into the room, put down the tray and went out, giving the patient no time to protest." He gave judgment for the plaintiff for £100 with costs.

Medical Practice a "Business"

If the judges have occasionally seemed to transcend the rules of common sense in their interpretation of words, no-one will quarrel with the decision of Mr. Justice Danckwerts[3] that, in the circumstances of the case before him, a medical practice could be a "business." A father bequeathed a substantial part of his residuary estate upon trust so that money might be available for his son at the age of 35 "for the purpose of starting . . . in business or for the advancement of any business with which he may be concerned." The son had not qualified as a doctor at the date of the execution of the will. He qualified at the age of 34. After he was 35 the trustees asked the court whether they could lawfully apply the money for buying him a house to be used partly as his residence and partly as his surgery.

The learned judge said the clause should not be narrowly construed. Its object was to assist the son to maintain himself in a gainful occupation. Both the dictionaries and the reported decisions suggested that the word "business" was capable of including a profession. His lordship took note of the fact that the old method of buying a practice had now been altered; but he found evidence that it was often a condition of success that a doctor could take over a residence. Plainly his chances must be affected by his ability to acquire premises for his surgery and for consultation. He held that the trustees might buy a house in which the son could reside, but it must not be merely a family residence; it must be purchased with a view to advancing his prospects in the medical profession.

In England Now

A Running Commentary by Peripatetic Correspondents

What struck me most at Canvey Island was how well all those concerned with rescue work or resuscitation had stood up to a long period of stress, anxiety, and lack of sleep. Their capacity for grappling with problems and for paying minute attention to detail seemed to be enhanced rather than diminished. The only sign of impaired efficiency I noticed was a tendency to loss of memory for recent events. For example, one very tired worker asked a doctor at least six times in a quarter of an hour if he was short of a particular article. But the prevailing mood inclined to elation, and unwarranted laughter was a common sign of strain. Appetites seemed to be bigger, and, not surprising to anyone who has served with the Armed Forces, enormous quantities of tea were consumed.

The psychological picture of the victims of this disaster was not unlike that of victims of the blitz. But their apathy was striking. Whether this was due to exposure and cold, a reaction to a state in which past and future are momentarily lacking in impact on the mind, or to some factor inherent in the flood experience itself, is a matter for conjecture. Some showed a tendency towards dissociation, and fastened an effect on to an emotionally indifferent object instead of the real source of grief. One mother, for instance, whose child had been killed bemoaned the loss of a new wireless set. A brittle brightness was quite usual, and I only saw one case of frank hysteria—a young man who quickly responded to sedation. It seems, however, that some of these people may need some form of abreaction. The disaster bore heavily upon the extremes of life, and I have carried away a vivid picture of the effect of a large bundle of comics and sweets being given to some children. The improvement in their general state was dramatic.

But one thing Canvey Island has done for me is to change completely my views about general practice. The work of the local doctors was impressive in its competence though many of them had worked non-stop without sleep for 48 hours. And their devotion to their patients was equalled by the confidence in which their patients held them. The therapeutic value of the very presence of these men, known and trusted, familiar faces in an unfamiliar world, was something which mere technical ability could not equal. This was not the time for bottles of medicine, letters to outpatient departments, nor applied psychology, but a striking reminder that, at any rate in some circumstances, and probably in more than most of us like to think, the man is more important than his methods.

* * *

So the longest and least loved month of the year has ended and no-one is sorry. December we tolerate because of Christmas and the few days snatched from our youth which it brings us. February we endure because it is short and, even more, because it is the forerunner of spring. But January has nothing. As one of my patients from her wisdom of 96 years remarked: "It seems longer than it is because we tack on the last few days of December to its beginning." And come to think of it we do. There are the carols and turkeys and all the festivities of Christmas Day, followed by the distended tummies and thank-you letters of Boxing Day. Then after a brief hiatus the shops reopen, all signs of Christmas gone and their windows full of their January sales. We think of our income-tax, our telephone and gas bills. We replenish the coal cellar, put anti-freeze in the radiator, and generally gird up our loins and prepare for the worst. When the New Year at last appears Christmas seems months away, and in our own minds we are well on with the winter. Then comes the snag: January has still 31 more days to run. We realise once again that figures lie and that whatever the calendar says the first month of the year is as ever twice as long as any of its fellows.

* * *

A professional call at the nurses' home is a formal affair. When I am wanted, a duly authorised person notifies my office. Plenipotentiaries then negotiate until they agree on a mutually convenient quarter of an hour—

Royal College of Surgeons of England

Prof Reynaldo dos Santos (Lisbon) has been elected to the honorary fellowship

Royal Faculty of Physicians and Surgeons of Glasgow

At a meeting of the faculty on Feb 2, with Dr Andrew Allison, the president, in the chair, A H Edwards was admitted a fellow (qua surgeon)

C M F /M E F Physicians' Reunion Dinner

This dinner will be held on Saturday, March 28, at Simpson's in the Strand, with Dr D Evan Bedford in the chair Further information can be had from the hon secretary, Dr A Willcox, 59, Harley Street, London, W 1

Colyer Prize

An award of this prize will be made this year It is offered for the best original work in dental science by a dental surgeon educated at a dental school in Great Britain or Northern Ireland who has not been qualified more than five years Applications should be sent to the prize committee of the Royal Society of Medicine, 1, Wimpole Street, London, W 1, not later than Sept 21

The Horder Club

This club was formed about six years ago to honour Lord Horder and his work on the rheumatic diseases It is comprised of a group representing many of the facets of the study of the rheumatic diseases and includes general physicians and, physicians interested in rheumatology and physical medicine, together with orthopædists and radiologists It is hoped soon *to add one or more men primarily interested in the basic* sciences The club met on Jan 29 and discussed a film shown by Dr Campbell Golding, illustrating some features in the radiographic study of rheumatoid arthritis The hon secretary is Dr Ernest Fletcher, 41, Harley Street, London, W 1

advice on the domestic care of the infectious diseases commonly nursed at home.

Although there is little difference in the health conditions north and south of the Border, it seems that the Scottish General Nursing Council intends to continue the registration of fever-trained nurses. It may be that the future gaps in the English nursing service will have to be filled by the importation of fever-trained nurses from Scotland, or alternatively that nurses from England will have to travel northwards to secure acknowledgment of this valuable branch of nursing experience.

Although the common infectious diseases are in a period of decline, the threat of their renewed prevalence must always remain. The ever-present possibility of smallpox or typhoid fever in widely spread epidemics, the potential renewal of virulence in some of the common infectious diseases, and the present prevalence of virus infections such as poliomyelitis call for many nurses trained in handling infectious diseases. In a very few years the reserve of such nurses will be seriously depleted—a position which should cause the utmost concern to all those responsible for the health of the people.

JAMES GRANT
Medical Officer of Health and Medical
Superintendent, Sheriff Hill
Infectious Diseases Hospital.

Gateshead.

SIMULTANEOUS AORTIC AND AXILLARY EMBOLISM

SIR,—Mr. Hardy and Mr. Noon are to be congratulated on their skilful management of their quite remarkable case of aortic and axillary embolism. Their discussion of the case (Jan. 24) will be of great interest to any surgeon who may be called on to undertake this operation. I should like to endorse all their points and also to venture one or two comments based on experience of 11 cases of peripheral embolism, including 4 cases of aortic embolectomy in 2 of which the patient recovered from the operation.

Certainly extreme care and gentleness is essential in handling and sewing vessels smaller than the aorta. Although extrusion of the embolus and clot by milking is to be preferred to endarterial manœuvres, there are occasions when clot remote from the exposed vessel requires removal by suction. I found my ball-ended needle more effective than a catheter for this purpose,[1] and it has since been valuable on several occasions. In aortic embolectomy it is an advantage when possible to have one assistant in control of the aorta and another standing between the abducted legs in control of the common iliac vessels.

I believe it is very important during the first three to four postoperative days to use all proved methods of relaxing vascular spasm and increasing the collateral circulation. In addition to those mentioned by Mr. Hardy and Mr. Noon, including the valuable technique advised by Mr. Kinmonth,[2] I believe that lumbar sympathetic block should be done twice daily and also an intra-aortic injection of papaverine given in saline. This injection can easily be carried out at the same time as the left paravertebral injection.

This treatment results in noticeable improvement in the limb circulation, and has been used in 2 cases of femoral embolectomy in the last two months. In the late case of femoral embolism these and other measures, such as the oxygen tent, may contribute to the saving of a limb.

One last point of interest is that I have injected at laparotomy 5 ml. of 10% phenol along the lumbar sympathetic chains through the posterior peritoneum in some elderly patients who have also been suffering from the effects of senile obliterative arteritis of the lower limbs. This simple procedure has given effective sympathetic release, and it may therefore be worth while in cases of aortic embolectomy.

Whipps Cross Hospital,
London, E.11.

D. LANG STEVENSON.

POLIOMYELITIS

SIR,—I agree with Professor Trueta in his comments (Jan. 31) on your abstract (Jan. 10) of Dr. Ritchie Russell's book. I am interested in Dr. Ritchie Russell's views on the defects of prolonged hospital treatment, but feel that he is not just in his assessment of orthopædic practice.

Anterior poliomyelitis remains an enigmatic disease despite the work done during the past half-century. Ritchie Russell has emphasised the need for fresh and unbiased inquiry into all its aspects. While the approach with an open and inquiring mind is valuable, weight should be given to the experience of those who have been concerned with the long-term treatment of the disease for many years. A certain school of orthopædics has unjustly been blamed for advocating rigid splintage, but it is certainly true that in the past, for a reason that no longer applies, the older orthopædic teachers did prolong immobilisation unnecessarily when the acute illness was past. This practice derived largely from the view that if structure was preserved functional restoration would be facilitated. Certainly by these means they prevented the ghastly deformities which developed in the absence of any treatment.

This conflict between the claims of structure and of function has lasted for at least two centuries since John Hunter (quoted by Wood Jones) stated that " it is a vain quest to attempt to solve any of the problems connected with living organisms by studying only one of the twin factors that constitute the basis of life." If we could only regard function as, so to speak, the fourth dimension of structure many therapeutic problems would be easier.

The following are some of the disturbances which cause disability in poliomyelitis. I find it impossible to distinguish the precise contribution of each to structural or to functional disability, because they are inseparable. The most important feature is that which Steindler calls myogenic contracture, and to this the following contribute:

1. *Muscular disuse and reciprocal over-action.*—The weakness of affected muscles and the over-action of antagonists as a cause of deformity is less often seen nowadays, except in untreated poliomyelitis. It probably is less important than other factors.

2. *Muscle spasm.*—This is a transitory phenomenon, the cause of which is not clear. It has been found in partly paralysed muscles as well as those relatively unaffected, but is absent in totally flaccid muscles. It has been ascribed to local irritability of muscle tissue, a myositic element, or various types of neuroanatomical disturbance.

3. *Muscular atrophy and fibrous replacement.*—These changes that follow denervation appear to be the same as those in the later stages of badly treated peripheral-nerve injury. In poliomyelitis such degenerative changes are diffuse and variable in intensity. They would seem to be due to changes in elasticity, which normally is a quality of the non-muscular connective-tissue elements of muscle.

4. *Osteomyotatic aplasia.*—This factor operates only in childhood. The term is, perhaps, cumbersome. By it I mean the failure of the normal stimulus to muscle-fibre growth. According to the work of Wheeler Haines, the length of muscle-fibres is determined by the extending force of growing bone. Such an influence on deformity is, I think, evident in calf-muscle paralysis, where the absence of an upward distracting influence by the os calcis prevents the growth of the plantar muscles. Relative shortening or aplasia of this type in functioning muscles may contribute to talipes calcaneus and paralytic scoliosis. This is not a question of muscular over-action but of failure to grow in length.

tion of sodium usually fall, but the potassium increases in concentration and amount (Annis and Alexander 1952). Although much of the potassium in stools may be bacterial and unavailable for reabsorption, the experiments with urine suggest that the colon can absorb sodium, but not potassium. This must operate in favour of enhancing potassium loss, and diminishing sodium loss, although there is ample evidence that in really copious diarrhœa sodium conservation by the colon is overborne. Quite apart from these local factors making for a higher potassium loss relative to sodium than would be predicted from analysis of isolated secretions, there are general factors which make the body more vulnerable to potassium than to sodium depletion, in the sense that any given external deprivation of potassium will produce a greater intrinsic depletion than would the corresponding external deprivation of sodium. Notable among these is the relative inefficiency of the kidneys in conserving potassium in response to depletion (Tarail and Elkinton 1949). There is no doubt that the kidney can conserve potassium by excreting a urine of lower potassium concentration than plasma (Mateer et al. 1949, Fourman 1952), and the progressive renal conservation of potassium is quite clearly seen in normal subjects on a very low potassium intake (Black and Milne 1952). As a rule, however, in clinical potassium depletion the urinary excretion of potassium remains considerable, although not so high as in the normal person. The occasional competence of the kidney to conserve potassium suggests that its usual failure to do so may be largely conditioned by extrarenal factors. These include glycolysis, protein breakdown, and acidosis, all of which make potassium from cells available for excretion. Acidosis may have a more direct action on the kidney itself, in that potassium may be drawn on as a base for excretion with fixed acid. The extent to which the adrenal cortex is overactive in disease states is still a matter of considerable controversy; an increased output of cortical hormones would increase renal excretion of potassium and diminish that of sodium, and to that extent might be operative in equalising sodium and potassium deficits even when the extrarenal loss of sodium was greater.

Loss of Potassium in the Urine

Although gastro-intestinal disease, including steatorrhœa (Harrison et al. 1943), was the earliest recognised cause of clinical potassium depletion, and remains the most frequent, potassium depletion has been demonstrated in other types of disease, the common factor being an abnormal loss of potassium in the urine. As with sodium, diminished intake of potassium plays only a subordinate part as compared with abnormal loss. The precise part played by the kidney itself in these abnormal urinary losses of potassium varies. Sometimes it is responding normally to a shift of potassium from cells into the extracellular fluid (E.C.F.); at other times it seems to be more directly "at fault," in that it excretes potassium from an extracellular fluid which is apparently normal in respect of that ion, or even depleted. This may happen under the influence of hormones or foreign substances, or because of intrinsic renal disease.

The distinction between what we may call "metabolic" and "renal" loss of potassium in the urine may not be easy to make; for one thing, the kidneys are part of the body, and the tubule cells are subject to the same hormonal stimuli as the other body cells. Also, a primary renal loss of potassium will induce a secondary transfer of potassium from cells to extracellular fluid, and conversely metabolic release of potassium soon involves renal mechanisms of increased excretion. Even in a condition so ostensibly "metabolic" as diabetic keto the loss of potassium from the body is only partly related to release of potassium from the cells due to acidosis, glycogen depletion, and protein breakdown; it is certainly augmented by the renal effects of acidosis and osmotic diuresis (Brodsky and Rapoport 1951), and also possibly by increased adrenocortical activity (Stowers 1951). In spite of such difficulties, it is still possible to find examples of potassium depletion which are predominantly "metabolic" in origin, and others which are "renal." In the first group we may include the potassium depletion associated with tissue breakdown (Howard and Carey 1949), primary water depletion (Black, McCance, and Young 1944, Elkinton and Winkler 1944), and mobilisation of glycogen stores (Fenn 1939). The potassium depletion induced by saline infusion (Coller et al. 1945), or observed postoperatively (Pearson and Eliel 1949) is probably of mixed metabolic and renal origin, like that in diabetic coma. The excretion of potassium by normal kidneys is increased by deoxycortone or by natural adrenal cortical hormones, as in Cushing's syndrome; potassium excretion is also increased by *p*-aminosalicylic acid (Cayley 1950), by liquorice (Strong 1951), and by mercurial diuretics (Blumgart et al. 1934). In primary renal failure, potassium wastage is uncommon, although paralysis related to potassium depletion has been described (Brown et al. 1944). Usually potassium excretion remains adequate to keep the serum-potassium normal, in spite of the greatly reduced glomerular filtration of this ion; secretion of potassium by the tubules can sometimes be inferred from an excess of excreted over filtered potassium (Platt 1950). Potassium depletion of renal origin, in the absence of uræmia, has been reported in renal tubular acidosis and the de Toni Fanconi syndrome (Milne, Stanbury, and Thomson 1952), and in the "early diuretic phase" of recovery from anuria (Bull, Jockes, and Lowe 1950). Potassium depletion observed in association with chronic alkalosis may also be of renal origin (Stanbury and Thomson 1952).

Recognition of Potassium Depletion

Knowledge of the various mechanisms which can lead to potassium depletion is of considerable importance, since the clinical picture is neither obtrusive nor well defined, except for paralysis which is by no means a constant finding. Moreover, the biochemical demonstration of potassium depletion may be far from easy in the individual patient; for the serum level of potassium may be within the rather wide normal range of 3.5–5.6 m eq per litre (Wootton et al. 1951) or may even be raised, when concurrent sodium depletion has reduced the E.C.F. volume at a time when potassium is streaming out of the cells (Danowski et al. 1949). On the other hand, the serum-potassium may be low in the absence of a general body deficit of potassium owing to an excessive uptake of potassium into cells. This may happen spontaneously, in periodic paralysis (Danowski et al. 1948), or secondarily

AUGMENTED RESPIRATION

SIR,—Dr. O'Brien, in his letter (Jan. 31), questions the value of our method of treating atelectasis neonatorum on the ground that other "less ingenious" methods of artificial respiration have persistently failed. This is not good logic, and he can hardly advocate the abandonment of further attempts to meet this most serious emergency.

Experimental work by Day et al., to which he refers, has shown that full-term fœtal atelectatic lung can be satisfactorily inflated; and Dr. O'Brien misrepresents the purport of this important article. They failed, however, in the case of gross structural immaturity. In the case of hyaline membrane Potter could not re-expand affected lung post mortem with air, nor do we yet know whether this condition is reversible in the living subject.

Recently Dr. O'Brien and Dr. Roberts[1] described resuscitation of the newborn by intermittent positive endotracheal inflation. The usefulness of this method in the immediate treatment of asphyxia in full-term infants has long been generally accepted since Gibberd and Blaikley first introduced it. Nevertheless the danger of overdistension of the alveolar ducts likewise applies. As described by O'Brien and Roberts, however, oxygen, delivered at $1\frac{1}{2}$ litres per minute, is intermittently supplied at an empirical rate which bears no relation to the child's requirements or spontaneous efforts, if any, and at pressures which are neither accurately determined nor controlled.

Dr. O'Brien suggests that our treatment not only fails to assist a baby in breathing but even accelerates the development of factors responsible for atelectasis. This criticism is no more than conjectural and is not based on observations comparable to our own with the servo respirator in action. He alludes to the possible fate of normally aspirated liquor amnii, but if a baby can be kept alive and breathing it has a chance of dealing with this in the physiological manner. Our use of negative pressures is also likely to improve circulation by encouraging rather than opposing venous return to the heart.

We believe that it often takes several hours of treatment to overcome atelectasis by gradually assisted expansion; and we have, in the past, from time to time failed to save the child by stopping treatment too soon after witnessing clinical improvement. Since our article appeared, two further severely affected cases, in which the prognosis appeared very grave, have been successfully treated in the servo respirator and are doing well.

We did not state, as represented by Dr. O'Brien, that atelectasis found at necropsy is unrelated to the ante-mortem state; but we produced instances to show that, in some cases, total non-aeration of the lungs may be found post mortem where evidence of at least some degree of aeration has been present before death—an observation already made by Potter.

Our trip spirometer is calibrated on each occasion it is used by means of pumping air into it with a well-lubricated 10 ml. syringe, using the same non-return valves. Mask leaks are tested for by gently compressing the sides and observing pen deflection. The alginate seal, when used, forms a far more natural and complete seal than any inflated cuff; and, provided it is not being subjected to pressures, it permits the minimum of leakage. For many months now we have taken the precaution of switching off the respirator pressures for the taking of recordings.

We do not claim the accuracy of a physiological experiment and have already listed the limitations of the method, many of which are due to the mechanics of the writing pens; but plans to improve these defects are already well under way. As it is, the method, though rough and ready, is simple, can be operated by a nursing sister, and causes the minimum of disturbance to a sick child.

Basal conditions are not applicable in the face of respiratory distress, and maximal respiratory capacity is more indicative of the child's ability to survive. It would be wanton to forgo any contributory information, thus available, in making a clinical assessment; and Dr. O'Brien's objections ignore the practical needs of the case.

Let us not widen the existing gap between scientific experiment and clinical reality.

TUBERCULIN SENSITIVITY

SIR,—Having been ill for some time, I have only now been able to study the intriguing paper by Dr. Edwards and Dr. Palmer (Jan. 10). They claim that "low-grade" tuberculin sensitivity is non-specific, and they repeat this postulate so clearly in their article that there is no doubt they mean it is *always* non-specific. Prior to discussion of this surprising postulate, there is one question which I think they should answer.

Do they believe that, after a first tuberculous infection, specific skin allergy will invariably remain at what they term a high level throughout life, regardless of whether the focus heals or not, and even if the individual never undergoes a further infection? If they believe this, what are the grounds for their belief? To put it more directly, do they disbelieve that after a first tuberculous infection, and in the absence of further infection, specific cutaneous allergy may through the months and years gradually wane to a very low level? For if it does so wane, surely it must pass through a stage of reacting only to high doses of tuberculin and so constitute "low-grade" sensitivity within their definition.

MARC DANIELS.

EFFECTS OF A SEVERE FOG ON A GENERAL PRACTICE

SIR,—I was interested to read Dr. Fry's article in your issue of Jan. 31. The figures given by him concerning the increase in the volume of work surprised me in more ways than one.

Firstly, an increase of 50 cases a week in a practice of 4500 indicates that only slightly more than 1% were affected as a result of the fog. This is a comparatively trivial figure compared with a similar occurrence in my practice two or three years ago when the volume of work increased to such an extent that I attended 45% of my entire list (2600) in a week.

Secondly, I am surprised at the relatively small amount of work indicated as normal for the practice concerned. Dr. Fry's figures show his yearly items of service as approximately: visits 3900, attendances 13,000; total 16,900. My own figures for a practice of 2600 people show the following: visits 11,900, attendances 18,700; total 30,600. In other words Dr. Fry's rate of remuneration per item of service is approximately three times mine. Can you, Sir, offer any suggestions as to how this great disparity arises?

Whitburn, co. Durham.

FRANK CORT.

*** This letter has been shown to Dr. Fry, who replies as follows:

"The main purpose of my short report on the effects of the severe London fog was to show what type of *clinical material* was encountered during the period. It was *not my intention* to show how much or how little work my practice entailed during a year. This has been discussed in a previous report.[1]

"It is, I believe, quite impossible to judge the worth and quality of a practitioner by the volume of work that he does. Obviously this volume will depend on very many factors, such as (1) the type of practice and the nature of the diseases

tion of sodium usually fall, but the potassium increases in concentration and amount (Annis and Alexander 1952) Although much of the potassium in stools may be bacterial and unavailable for reabsorption, the experiments with urine suggest that the colon can absorb sodium, but not potassium This must operate in favour of enhancing potassium loss, and diminishing sodium loss, although there is ample evidence that in really copious diarrhœa sodium conservation by the colon is overborne Quite apart from these local factors making for a higher potassium loss relative to sodium than would be predicted from analysis of isolated secretions, there are general factors which make the body more vulnerable to potassium than to sodium depletion, in the sense that any given external deprivation of potassium will produce a greater intrinsic depletion than would the corresponding external deprivation of sodium Notable among these is the relative inefficiency of the kidneys in conserving potassium in response to depletion (Tarail and Elkinton 1949) There is no doubt that the kidney can conserve potassium by excreting a urine of lower potassium concentration than plasma (Mateer et al 1949, Fourman 1952), and the progressive renal conservation of potassium is quite clearly seen in normal subjects on a very low potassium intake (Black and Milne 1952) As a rule, however, in clinical potassium depletion the urinary excretion of potassium remains considerable, although not so high as in the normal person The occasional competence of the kidney to conserve potassium suggests that its usual failure to do so may be largely conditioned by extrarenal factors These include glycolysis, protein breakdown, and acidosis, all of which make potassium from cells available for excretion Acidosis may have a more direct action on the kidney itself, in that potassium may be drawn on as a base for excretion with fixed acid The extent to which the adrenal cortex is overactive in disease states is still a matter of considerable controversy an increased output of cortical hormones would increase renal excretion of potassium and diminish that of sodium, and to that extent might be operative in equalising sodium and potassium deficits even when the extrarenal loss of sodium was greater

Loss of Potassium in the Urine

Although gastro-intestinal disease, including steatorrhœa (Harrison et al 1943), was the earliest recognised cause of clinical potassium depletion, and remains the most frequent, potassium depletion has been demonstrated in other types of disease, the common factor being an abnormal loss of potassium in the urine As with sodium, diminished intake of potassium plays only a subordinate part as compared with abnormal loss The precise part played by the kidney itself in these abnormal urinary losses of potassium varies. Sometimes it is responding normally to a shift of potassium from ce into the extracellular fluid (E C F), at other times seems to be more directly "at fault," in that it excret potassium from an extracellular fluid which is apparent normal in respect of that ion, or even depleted This m happen under the influence of hormones or foreig substances, or because of intrinsic renal disease

The distinction between what we may call "metabolic and "renal" loss of potassium in the urine may not easy to make, for one thing, the kidneys are part of t body, and the tubule cells are subject to the sa hormonal stimuli as the other body cells Also, a primar renal loss of potassium will induce a secondary transf of potassium from cells to extracellular fluid, and co versely metabolic release of potassium soon invok renal mechanisms of increased excretion Even in condition so ostensibly "metabolic" as diabetic keto the loss of potassium from the body is only part related to release of potassium from the cells due acidosis, glycogen depletion, and protein breakdown it is certainly augmented by the renal effects of acidos and osmotic diuresis (Brodsky and Rapoport 1951), an also possibly by increased adrenocortical activi (Stowers 1951) In spite of such difficulties, it is sti possible to find examples of potassium depletion whic are predominantly "metabolic" in origin, and other which are "renal" In the first group we may includ the potassium depletion associated with tissue breakdow (Howard and Carey 1949), primary water depletio (Black, McCance, and Young 1944, Elkinton an Winkler 1944), and mobilisation of glycogen store (Fenn 1939) The potassium depletion induced by salin infusion (Coller et al 1945), or observed postoperativel (Pearson and Eliel 1949) is probably of mixed metabol and renal origin, like that in diabetic coma The excretio of potassium by normal kidneys is increased by deox cortone or by natural adrenal cortical hormones, as i Cushing's syndrome, potassium excretion is al increased by *p* aminosalicylic acid (Cayley 1950), b liquorice (Strong 1951), and by mercurial diuretic (Blumgart et al 1934) In primary renal failure, potassium wastage is uncommon, although paralysis related to potassium depletion has been described (Brown et al 1944) Usually potassium excretion remains adequate to keep the serum-potassium normal, in spite of the greatly reduced glomerular filtration of this ion, secretion of potassium by the tubules can sometimes be inferred from an excess of excreted over filtered potassium (Platt 1950) Potassium depletion of renal origin, in the absence of uræmia, has been reported in renal tubular acidosis and the de Toni-Fanconi syndrome (Milne, Stanbury, and Thomson 1952), and in the "early diuretic phase" of recovery from anuria (Bull, Joekes, and Lowe 1950) Potassium depletion observed in association with chronic alkalosis may also be of renal origin (Stanbury and Thomson 1952)

Recognition of Potassium Depletion

Knowledge of the various mechanisms which can lead to potassium depletion is of considerable importance, since the clinical picture is neither obtrusive nor well defined, except for paralysis which is by no means a constant finding Moreover, the biochemical demonstration of potassium depletion may be far from easy in the individual patient, for the serum level of potassium may be within the rather wide normal range of 3 5–5 6 m eq per litre (Wootton et al 1951), or may even be raised, when concurrent sodium depletion has reduced the E C F volume at a time when potassium is streaming out of the cells (Danowski et al 1949) On the other hand, the serum potassium may be low in the absence of a general body deficit of potassium, owing to an excessive uptake of potassium into cells This may happen spontaneously, in periodic paralysis (Danowski et al 1948), or secondarily certain movement, thereby pressing into activity unhabituated muscle groups, is probably being imprudent and facing risk. Accepting this proviso, there seems to be no good reason why the new swing should not be practised, since it is a pleasure to execute and gives the golfer more power and control.

In view of the new provisions for promoting golfing prowess in the young, it would be useful to know how far (if at all) the objections to the new swing are well founded.

London, W.1. MICHAEL ALBURY.

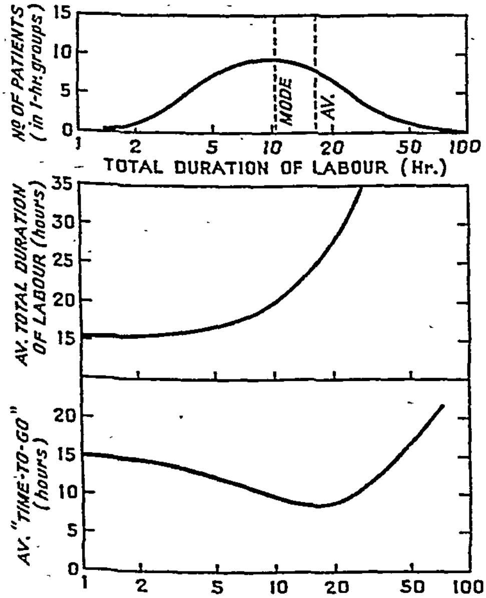
EXPECTATION OF FURTHER DURATION OF LABOUR

SIR,—In deciding on treatment in cases where labour is proving to be slow, it would be helpful to know the average further duration of labours in like circumstances. Averages must take account of such factors as the strength and frequency of uterine contractions, the rate of dilatation of the cervix, minor degrees of disproportion, and unusual presentations. Data are still insufficient for full sets of figures; and, moreover, the values are probably specific for a given location and epoch. Values can, however, be prepared for various parities, and the curve reproduced in the accompanying figure is for primiparæ.

Curve 1 shows the number of patients delivered after labours lasting for various times. The figures were collected from a group of 370 normal deliveries by counting the patients in each 1-hour group. The modal value is 10 hours, but the average value is higher than this (16 hours) owing to the inclusion of long pathological labours. This curve is similar to those published by Busby.[1]

Curve 2 shows for various times the average length of labour of all patients still undelivered at a given time. It commences at 16 hours and rises to 28 hours' total labour for all patients undelivered after 20 hours.

Curve 3 shows the average "time-to-go." It is obtained by subtracting the time already spent in labour from the figures of curve 2. Time-to-go has an average at the start of labour of 16 hours; after 10 hours the further expectation has fallen to 10 hours; there is a minimum expectation at 16 hours of a further 8 hours; and after this the curve rises steeply owing to the large percentage of pathological cases in the remaining patients.



A, number of primigravidæ, in a group of 370, delivered after different times. B, average total length of labour in primigravidæ, according to time already in labour. C, average further duration of labour in primigravidæ, according to time already in labour.

This graph emphasises the need for early action to prevent long labours. A primigravida who is still in the first stage of labour after having regular contractions for 16 hours needs to have her case carefully reviewed.

THE MEDICAL SERVICES IN THE KOREAN WAR

SIR,—The letter from General Sir Neil Cantlie last week adds little to the report by your correspondent on Jan. 17. Your correspondent stated: "Our own units have continued to use plasma as the chief means of replacing colloids and electrolytes in initial treatment." He also added: "The Americans have depended more on fresh blood."

In my previous letter (Jan. 24) I pointed out that during the late war, when ample supplies of blood and plasma were available, experienced workers in the forward areas used more than twice as much blood as plasma. Apparently this is also the practice of the American medical services today. It is difficult to understand why it is not also the practice of the Commonwealth medical services, and, in the absence of any explanation, one is regretfully forced to the conclusion that blood is not as readily available to the Commonwealth medical units in Korea as it should be.

Hove. REX BINNING.

Parliament

Hospital Endowments (Scotland) Bill

IN the House of Lords on Feb. 5 Earl FORTESCUE, on behalf of the Earl of HOME, Minister of State, Scottish Office, introduced this Bill, which provides for the constitution of a Scottish hospital endowments research trust. It also empowers the Hospital Endowments Commission to transfer endowments to the trust. The Bill is based on the recommendations of the Hospital Endowments Commission,[1] set out in a white-paper last August.

QUESTION TIME

Industrial Dermatitis Appeals

Mr. J. T. PRICE asked the Minister of National Insurance if, in cases of industrial dermatitis referred to medical appeal tribunals, the medical members appointed to adjudicate were in all cases qualified dermatologists.—Mr. R. H. TURTON replied: I could not accept the suggestion that medical appeal tribunals should always include specialists in the particular condition from which an appellant may be suffering. But in a case of dermatitis the evidence before the tribunal always includes a report by a dermatologist.

Mr. PRICE: Would the Minister not agree that it is considered by people well qualified to judge that in discussing or adjudicating upon these difficult cases the presence of general physicians who have no dermatological qualifications is quite useless, because these cases involve questions not only of disease but of medicolegal fact which has a bearing on the decisions made? Is the Minister aware that there is a good deal of disquiet about the manner in which these cases are being disposed of at the moment?—Mr. TURTON: The Ministry have not had such indications. There is general satisfaction with the decisions of the medical appeal tribunals, which consist of physicians of very great eminence. The adoption of any suggestion such as that made by the hon. member would involve a great delay in the treatment of these cases.

Tuberculosis among Women in Scotland

Replying to a question, Commander T. G. D. GALBRAITH, joint under-secretary of State for Scotland, said he was aware that for the 15–35 age-group in Scotland, contrary to the usual experience elsewhere in Europe, the female death-rate was higher than the male death-rate in the years 1948–50. This was due to the excess of female deaths from respiratory was replaced by hydrogen ions, giving a combined acidosis and potassium deficiency A further important difference between the two studies was that with actual ingestion of the resin Fourman was able to withdraw some potassium directly from the body, and also in his subjects urinary excretion of potassium remained high, presumably because of the acidosis, whereas in our subjects actual potassium loss was almost entirely urinary, and became rapidly curtailed For these reasons, his potassium deficit became much greater

---

[1] See *Lancet*, 1952, ii, 251.

Experimental Depletion

The detailed results of our experiments have already been published (Black and Milne 1952), and here I shall only summarise the main findings, and discuss one or two conclusions which I think can be drawn from them and are of some general interest Two normal subjects were put on a diet containing less than 10 m eq of potassium daily, in contrast to a normal dietary intake in the preliminary periods of 140 m eq daily In spite of the low intake, both subjects continued at first to excrete sizable amounts of potassium in the urine, and the cumulative loss of potassium was 268 and 289 m eq in the two subjects The rapid initial loss of potassium soon diminished, and by the sixth day both subjects were very little removed from balance, even with the low intake used The low urinary excretion of potassium continued into the after-period, in which a high potassium intake was given, under these conditions, potassium was retained to an amount considerably greater than the pre existing deficit The serum potassium fell progressively as the potassium depletion increased, and under our experimental conditions the serum-potassium level was negatively correlated with the cumulative negative potassium balance ($r = -0\ 762$, $P < 0\ 01$) This relationship is of course commonly departed from in clinical conditions where potassium depletion is complicated by a diminished E C F and plasma volume, the results of concurrent sodium depletion

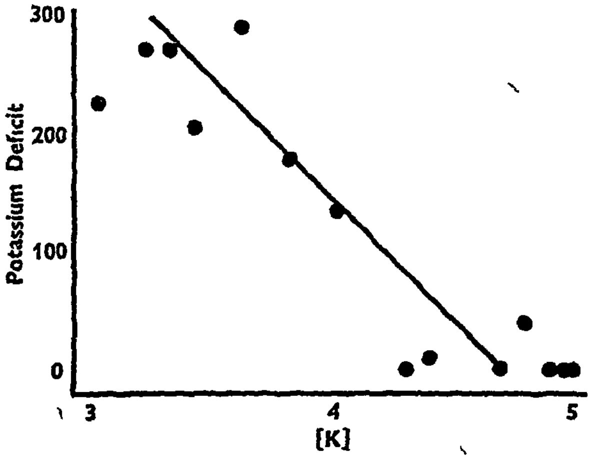

Fig 4—Relation between body potassium deficit and serum-potassium concentration

The fall in serum-potassium coincided with a rise in serum-bicarbonate, and there was a negative correlation between them ($r = -0\ 89$, $P < 0\ 01$), the possible significance of this finding will be discussed later Serum levels of sodium and chloride showed small changes, diverging sufficiently to accommodate the increment in bicarbonate The urine became less acid during the resin periods, and the output of ammonia and titratable acidity fell, these urinary changes are at least in part related to a diminished intake of chloride during the resin period, during which sodium was supplied from the resin, and not in combination with chloride, as in the preliminary and after periods There was during the resin period a large retention of sodium, and even of chloride, although the chloride intake was lower during the resin period than beforehand When the potassium depletion was repaired, there was a corresponding sodium and chloride diuresis The balances showed no significant loss of calcium or magnesium, but during the resin period there were small losses of nitrogen and phosphorus The losses of both these substances were much smaller than would have been observed had potassium, nitrogen, and phosphorus been lost together in the proportions found in tissue cells There was no loss in weight during the period of potassium depletion

Some interesting comparisons can be made between our experience of potassium depletion and that of Fourman, in relation to the clinical question "Does moderate potassium depletion per se cause any notable symptoms?" In our experiments, there were no dramatic symptoms, except when one of us took 3 g of ammonium chloride, and felt rather ill after it Otherwise we were able to perform our normal tasks, it may be with diminished efficiency Our daily portion of 3 litres of sweetened milk was no more distasteful when we were short of potassium We had no muscular weakness, although the serum-potassium fell on one occasion to 2 6 m eq per litre The harmful effect of ammonium chloride tallies rather well with Fourman's more fully documented experience in this respect, and also with clinical observation During the resin period, when Fourman's subjects were both acidotic and potassium-depleted, they "felt and looked very ill, took their diet with extreme difficulty, and became absent minded and then confused" During the recovery period of his experiments, the acidosis receded within a few days, and the plasma-bicarbonate rose above control values, there was still considerable potassium depletion, but at this stage symptoms were not dramatic, although "the subjects were morose apathetic, and tired easily" One subject drove to North Wales and did some hill-walking, with a deficit of 600 m eq of potassium The experimental evidence may be summarised in the statement that moderate potassium depletion does not in itself cause severe symptoms, but it may do so when associated with acidosis

The relevance of these experimental findings to clinical medicine obviously depends on there being no great quantitative divergence between the experimental and the clinical deficits of potassium This criterion of relevance is satisfied, at least so far as acute clinical potassium depletion is concerned The actual potassium deficit in patients is unknown, but can be gauged from the retention of potassium observed during recovery Two such studies on patients recovering from diabetic coma give retentions ranging in one series from 130 to 450 m eq, with an average of 290 m eq (Danowski et al 1949), in another from 147 to 385 m eq with an average of 279 m eq (Nabarro et al 1952a) The observed retention of potassium in our two subjects was 415 and 348 m eq, and in Fourman's subjects there were deficits of 338, 674, and 839 m eq The experimental potassium deficits are therefore somewhat greater than those observed in acute clinical potassium depletion, but appreciably higher retentions, up to 1000 m eq, have been recorded in chronic potassium depletion associated with loss of gastro intestinal secretions (Martin et al 1951)

Acidosis and Potassium Depletion

How are we to explain the undoubted occurrence of symptoms related to potassium depletion in a proportion of patients recovering from diabetic coma, when experimental depletion of similar or greater magnitude causes no such symptoms? It may be that the acidosis which is still present into recovery is potentiating the low serum potassium as a cause of symptoms, acidosis seemed to have this action in both the experimental studies just quoted I have seen profound apathy and muscular

Even when he was in his 80's his work as a writer went on, and his books the *Mystery of Birth* and the *Mystery of Marriage*, were published in 1948 and 1949. During these last years he had made his home at St. Margaret's Hospital, and his impressive appearance and personality made him an object of veneration and awe to the local population of Doddington. He continued his consulting practice, and patients came to him from all over the country. He remained physically and mentally alert, and in 1951 he was in private correspondence with us on the implications of the Cassidy case and the Denning judgment, arguing very wisely that medical members of hospital staffs must be accorded full responsibility for their professional acts.

ARTHUR FREDERICK GOLDSMITH

M.R.C.S.

Dr. Goldsmith died on Jan. 27, at the age of 82, in Bedford, where he had been in practice for many years. His family had a long record of service in the town: for his father, Dr. G. P. Goldsmith, practised there for forty years and his elder brother, Dr. G. Harvey Goldsmith, was consulting ophthalmological surgeon to the Bedford County Hospital.

Dr. "Fred," after he qualified from St. George's Hospital in 1874, joined his father's practice. Much of his work lay among the poor, and his old patients still talk of his skill and never-failing generosity. When his father retired in 1904 he succeeded him as district medical officer under the board of guardians, and he was also appointed public vaccinator. Dr. Goldsmith was an enthusiastic church worker, and he was for many years a churchwarden at St. Paul's Church. After he retired in 1932 he and his wife at first lived in Cornwall, but some years ago he returned to Biddenham, near Bedford, where he died.

Births, Marriages, and Deaths

BIRTHS

ALEXANDER.—On Feb. 6, at Ellerburn, Nunburnholme Avenue, North Ferriby, East Yorks, to June Alexander, M.B. (née Tyson), wife of Gordon Alexander, M.B., D.PATH.—a son.

THOMPSON.—On Jan. 29, at Newcastle upon Tyne, to Dr. Margaret Thompson (née Swinburne), wife of Dr. R. B. Thompson, M.R.C.P.—a son.

Appointments

CANN, A. M. R., M.D. Lond., D.C.H.: senior M.O. (school health service), Kingston upon Hull.

CULLINGTON, D. E., M.A., M.B. Camb., D.C.H., D.P.H.: M.O.H., Barking, Essex.

EARLE, J. H. O., M.D. Lond.: consultant asst. pathologist, Royal Cancer Hospital, London.

FLEMING, A. CHALMERS, M.B. Durh.: deputy medical superintendent, Hortham Hospital, Almondsbury, near Bristol.

HILL, T. W., M.D. Glasg., D.P.H.: asst. school M.O., Middlesbrough.

JARRATT, GEORGE, M.B. Lond., M.RAD. Lpool, D.M.R.T.: asst. radiotherapist, Hogarth radiotherapeutic centre, Nottingham General Hospital.

LOVE, S. H. S., M.B. Belf., D.A.: consultant anæsthetist, Belfast H.M.C. group.

MINTO, C. N., M.B. Aberd., D.P.H.: M.O.H., Caithness, and district hospital officer, Northern Regional Hospital Board for Caithness.

O'REILLY, J. T. J., M.B. N.U.I., F.R.C.S.I.: surgeon, County Hospital, Waterford.

OWEN, R. G., M.R.C.S.: appointed factory doctor, Penygroes, Caernarvonshire.

SAVILLE, STEPHANIE, M.B. Dubl.: anæsthetic registrar, Bath group of hospitals.

WARRACK, A. J. N., M.B.E., M.D. Lond., D.T.M.&H.: consultant pathologist, City General Hospital Laboratory, Sheffield.

Colonial Service:

BOULGER, L. R., M.B. Manc.: pathologist, Nigeria.

DAVIES, [illegible] C., M.R.C.S., D.P.H.: A.D.M.S., Tanganyika.

GOTTLIEB, [illegible]RYSTYNA, M.B., Polish School of Medicine, Edinburgh: schools M.O., Northern Rhodesia.

GREEN, BARBARA, M.B., D.T.M.&H.: senior M.O., Nigeria.

HARDY, J. M. H. R., L.R.C.P.E.: police M.O., Mauritius.

ROMBEJKO, EDWARD, MED.DIP. Warsaw: M.O., St. Helena.

Newcastle upon Tyne Regional Hospital Board:

LEGGAT, P. O., M.D. Aberd., M.R.C.P.: consultant chest physician (asst.), Newcastle (East) tuberculosis administrative area.

LYALL, D. J., M.B. Aberd., D.A.: consultant anæsthetist (asst.), Tees-side H.M.C. group.

MCDONALD, ROBERT, M.B. Aberd., D.P.H., D.P.M.: consultant psychiatrist, St. George's Hospital, Morpeth, Northumberland.

Notes and News

THE APPEARANCE OF ANIMALS

SWIFTLY reviewing the different shapes, patterns, and colours of various forms of animal life, Professor Portmann[1] lays emphasis on the facts that: (1) the external appearance is no guide to the internal (external symmetry often hides internal asymmetry); (2) the shape of many animals is based (as any zoological schoolboy knows) on a repetition of similar segments (metamerism); (3) there are many odd resemblances between animal and vegetable shapes; and (4) as the brain increases with the evolution of higher forms of animals, so the decoration of the head, or alternatively of the caudal end of the body, increases, especially after the descent of the testes to an extra-abdominal position.

The author's main contention seems to be that decoration of the body increases with the evolving importance of eyesight and is then intended to enable members of a species to recognise one another visually. "In all these cases," he says, "we are presented with optical structures, organs to be looked at, the total appearance of which has a meaning only when it is appreciated as being directed towards a beholding eye." Later he speaks of "morphological elements which are correlated with a beholding eye in the same way as transmitters are with a receiving set which is tuned in to them."

Other colours and patterns help their owners as warning colours and as camouflage, and in molluscs and radiolarians (which cannot see one another) colours and patterns can be produced "without any relation to visibility." But Professor Portmann does not attempt to explain this, although he seems to recognise that some colours and patterns arise without any utilitarian import. This takes us back half a century to Hans Gadow, who pointed out that neither natural selection nor sexual selection could produce colours and patterns but could only determine which colours and patterns already produced would survive. Indeed Professor Portmann makes a similar statement. Mysticism, however, creeps in when he declares that those colours and patterns which have a visual use constitute a special organ whose function is to produce a visible effect.

DATE OF BIRTH

A FILM with this title has been made by the National Film Board of Canada and is being sponsored in this country by the Ministry of Labour and National Service. The film tells of the economic and social problems associated with the provision of employment for older men and women. It runs for 18 minutes, and copies may be hired from the Central Film Library, Government Building, Bromyard Avenue, Acton, London, W.3, or from the affiliated libraries in Scotland and Wales.

University of Oxford

At a convocation to be held on July 1 in connection with the Rhodes centenary it is proposed to confer the honorary degree of D.C.L. on Dr. W. G. Penfield, O.M., F.R.S., director of Montreal Neurological Institute and professor of neurosurgery in McGill University.

Royal College of Physicians of London

The following, having satisfied the censors' board, were elected to the membership on Jan. 29:

E. M. McLachlan, M.B. N.Z., R. J. Marshall, M.D. Belf., J. Q. Matthias, M.B. Lond., G. W. Scott, M.D. Lond., H. M. Sinclair, D.M. Oxfd, W. H. J. Summerskill, B.M. Oxfd, J. L. G. Thomson, M.B. Lond., Joan M. Wagner, M.B. Witwatersrand, M. H. Watson, M.B. N.Z., J. L. Whitby, M.B. Camb., J. C. Woodrow, M.B. Leeds.

These names should have been included in the list published last week.

Royal College of Physicians of Edinburgh

At a meeting of the college held on Feb. 3, with Dr. W. A. Alexander, the president, in the chair, the following were elected to the membership:

D. G. McIntosh, D. G. C. Whyte, M. P. Goel, L. S. C. Mendis, G. M. Baird, B. Bevan, D. P. Gupta, J. B. Gibson, A. D. Muldoon, F. C. [illegible] W. Frain-Bell, J. Paul, Go[illegible]n, J. M. Neilson, R. H. [illegible] I. H. Pullon, M. Dan, Z. H. El Massry, S. Sing, J. A. Chunn, J. L. Potter, S. J. Irani, P. Sobti.

[1] Animal Forms and Patterns: A Study of the Appearance of Animals. By ADOLF PORTMANN. Translated by HELLA CZECH. London: Faber & Faber. 1952. 25s.

in the depletion period, and this was only partially compensated by change in excretion, so the dietary change must have contributed to the extracellular alkalosis In subject 2, on the other hand, who had part of the sodium supplement as bicarbonate, the excretory change more than compensated for the dietary change, and the extracellular alkalosis cannot be attributed in any degree to the increased alkalinising action of the diet

These deductions from the (fixed base minus chloride) in diet and excretion are perhaps more simply arrived at from comparison of the sodium and potassium balance In subject 1 the positive balance of sodium was greater than the negative balance of potassium, indicating an increase in the total fixed base On the other hand, in subject 2 potassium was lost to a greater extent than sodium was retained, so that the fixed base content of the body decreased The extracellular alkalosis in subject 1 may thus have been partly caused by inadequate renal response to an alkalinising diet, but in subject 2 this explanation seems inadmissible, and we are faced with an alkalosis in extracellular fluid, but with an actual fall in the body content of sodium and potassium of the order of 60 m eq This would seem to require that the extracellular alkalosis be balanced by an intracellular acidosis, a possibility which we must now discuss

EXTRACELLULAR ALKALOSIS WITH INTRACELLULAR ACIDOSIS

The classical study of Darrow et al (1948) showed that in potassium-depleted rats the rise in serum-bicarbonate was closely correlated with changes in intracellular composition, notably the entry of sodium into the cells Further work by his group (Cooke et al 1952) has now shown that this replacement of intracellular potassium loss by entry of sodium is incomplete, only about two-thirds of the potassium deficit being made good by sodium Cooke et al suggest that hydrogen ions pass from the extracellular fluid to within the cells during potassium depletion, leaving an extracellular alkalosis This concept of an intracellular acidosis, caused by entry of hydrogen ions from the E C F, is supported by the observations of Gardner (1952) on the muscles of potassium-deficient rats He found that when the extracellular bicarbonate was increased there was at the same time a fall in intracellular bicarbonate and carbon dioxide tension, and the calculated intracellular pH fell from a control value of 6 98±0 08 to 6 42±0 05

Our own experiments did not include muscle biopsy, and so we can offer no proof of intracellular acidosis comparable in elegance to these results on animals However, it is difficult to see what other mechanism could explain the extracellular alkalosis in the subject who showed a net loss of base from the body, with no shrinkage in total body fluid In both subjects the amount of sodium which left the cells during recovery was substantially less than the amount of potassium which went in, suggesting that during depletion there was a " K–Na gap " of the type which would favour, or even necessitate, a hydrogen-ion shift The much greater loss of potassium than of phosphate from the cells would also suggest a fall in phosphate valency, such as would be promoted by the entry of hydrogen ions into the cells All these points are consistent with the mechanism proposed, but do not of course prove it

Therapeutic Implications

The evidence which I have so far presented suggests that acidosis increases the " penetration " of hypokalæmia as a cause of symptoms, and also that potassium depletion may be associated with an over-all acidosis even in the presence of a raised serum-bicarbonate If these submissions are accepted, it would appear logical to treat clinical potassium depletion by potassium in combination with anions which are oxidised in the body, such as lactate, citrate, or acetate These potassium salts are alkalinising in their effect Leonsins (1951) has suggested a mixture containing potassium bicarbonate, acetate, and citrate, 1 g of each to 8 ml of water (2 teaspoonfuls) I have had both personal and clinical experience of this mixture, it is much less nauseating than a comparable amount of potassium chloride, and the slightly alkaline taste can be disguised in fruit juice Given four times a day, it supplies 116 m eq of potassium When direct administration of potassium is contraindicated by a high serum level, as in the early treatment of diabetic coma, the acidosis should still be treated with sodium lactate, as advocated, among others, by Nabarro et al (1952b)

Potassium Depletion and Body-fluid

Let us now consider the alterations in body fluid accompanying experimental depletion of potassium

During the resin period, both subjects lost potassium, retained sodium and chloride, and showed no significant change in weight Most of the potassium must have come from the cells, for the potassium loss was several times greater than the estimated initial extracellular potassium, moreover, the concentration of extracellular potassium never fell below half the initial value Some of the sodium may have gone into cells, but it is unlikely that chloride did so Calculation of change in extracellular fluid volume from the chloride balance (Danowski et al 1951) indicated increases of 3 0 and 1 9 litres in the two subjects A fall in the hæmatocrit percentage, which was observed in both subjects, gives evidence of E C F expansion, independent of balance calculations In the recovery period, there was a considerable urinary loss of water and sodium, suggesting that the excess of E C F was then being excreted, at this time the hæmatocrit percentage rose again The loss of cell fluid, which had been masked during potassium depletion by expansion of E C F, then became apparent by weight losses of 4 0 and 2 6 kg in the two subjects The changes in body-fluid distribution in one subject, calculated from the chloride and water balance, are shown in fig 6 It is of interest that one of Fourman's subjects developed actual œdema of the legs and face, and œdema in association with potassium depletion has been observed clinically (Eliel et al 1950)

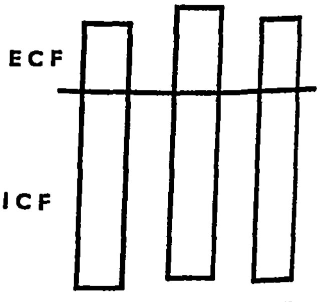

Fig 6—Changes in amount and distribution of body fluid in subject I

The calculated diminutions in intracellular fluid volume in our subjects agree fairly well with the amount of potassium known to be lost, and there is no evidence of a fall in the potassium concentration in the remaining I C F The absence of any notable change in serum sodium may be further evidence that the osmolarity of body-fluid, as opposed to its distribution, was not grossly altered On the other hand, with the more severe depletion associated with acidosis, Fourman and Ainley Walker (1952) found a loss of potassium which greatly exceeded the calculable volume change in I C F, and the concentration of potassium inside cells must have fallen Severe potassium depletion in animals is likewise associated with a fall in the potassium concentration of muscle I C F (Darrow et al 1948, Cotlove et al. 1952) The rather limited data available suggest that with potassium, as with sodium, the first effect of depletion on body-fluid is a shrinkage of the relevant compartment of body fluid, followed later by a fall in concentration, but we cannot exclude the possibility that the rather

BODY-FLUID DEPLETION*

D. A. K. BLACK
M.D., B.Sc. St. And., F.R.C.P.
LECTURER IN MEDICINE IN THE UNIVERSITY OF MANCHESTER

THERE is some truth in the statement that potassium stands in a relation to intracellular fluid similar to that which sodium bears to extracellular fluid. The great deposit of potassium lies within the cells, and the extracellular moiety of potassium is even smaller than the amount of intracellular sodium. Moreover, I hope to show later that potassium depletion, even of quite moderate degree, is attended by a diminution in volume of intracellular fluid (I.C.F.), and that with more advanced depletion the concentration of potassium in I.C.F. falls—quite a close functional analogy to what happens in sodium depletion to the volume and sodium concentration of extracellular fluid. There are, however, important differences, both quantitative and qualitative, between sodium and potassium in their respective phases of body-fluid. As we have seen, sodium accounts for over 90% of the base of extracellular fluid; but the predominance of potassium in intracellular fluid is less striking, for it forms at most two-thirds of the total base, the remainder being largely magnesium. Sodium is somewhat inert pharmacologically, so much so that in America it has been dubbed "osmotic stuffing"; but no-one has cared to take similar verbal liberties with potassium, in view of its well-known actions on neural transmission and muscular contraction. Even in a presentation mainly concerned with the relation of potassium to body-fluid, these pharmacological effects of the potassium ion demand some attention; but I cannot discuss them in the detail they deserve, and would refer you for this to the well-known review by Fenn (1940).

Physiologists have known for decades that lack of potassium in the surrounding medium will impair muscular contraction. The clinical counterpart to this is found in familial periodic palsy, whose centenary in description we may celebrate this year (Cavaré 1853). This relationship was first clearly established by Aitken et al. (1937), although with the spurious wisdom of hindsight we could commend Sir Farquhar Buzzard on his acumen in giving potassium tartrate to his patients in 1901. While these exciting discoveries were being made about extracellular potassium, the great mass of body-potassium lay neglected inside the cells, remote from direct analysis and untroubled by isotopes. Admittedly, balance studies commonly included potassium, as a measure of changes in intracellular fluid (Gamble, Ross, and Tisdall 1923); but the existence of potassium depletion involving mainly the cells was not established and shown to be clinically significant until the work of Darrow (1945). Darrow (1946) himself cites many examples in the literature, from as far back as Schmidt (1850), of diarrhœa associated with notable potassium loss. The observed losses often exceeded the total extracellular potassium, and must therefore have come in part from the cells; but the view that cell membranes were virtually impermeable to cations held sway, and inhibited any serious consideration of potassium depletion being predominantly an intracellular affair. By 1945, a dynamic approach to the problems of cell electrolyte composition had largely replaced the static schema centred on membrane permeability; and also by that time escape of potassium from cells had been demonstrated experimentally in several different contexts. For example, frog muscle in vitro lost potassium to the medium when this was made more acid or of lower potassium concentration (Fenn and Cobb 1934). Muscular contraction had been shown to be associated with loss of potassium (Fenn and Cobb 1936). Breakdown of glycogen or of tissue protein was known to be associated with discharge of potassium from the cells (Fenn 1940). Darrow's discovery of a large intracellular potassium deficit in infants with diarrhœa could therefore be readily accommodated in current theory—perhaps a necessary condition for the acceptance of all except the very greatest advances in knowledge.

By observing the retention of nitrogen and potassium during recovery, Darrow (1946) was able to show that potassium was retained in considerable excess of the amount which could be accounted for by tissue protein repair, as estimated from the positive nitrogen balance—a state of affairs which is often summarised in the phrase "retention of potassium in excess of nitrogen." Of the 6 infants studied, 2 had retention of potassium equivalent to 19% and 23% of the estimated normal potassium content of the body; the other 4 had retentions around 10% of the estimated total. Analysis of muscle from infants who had died from gastro-enteritis showed a potassium content up to 40% less than the normal. The inference that potassium deficits of this order should be treated by replacement therapy is supported by the findings of Govan and Darrow (1946). Of 53 infants treated by "conventional therapy" 17 died, whereas of 50 treated with potassium chloride in addition to the standard treatment, only 3 died.

Potassium Loss in Gastro-intestinal Disease

It was appropriate that the first clear demonstration of gross potassium depletion should have been made on gastro-intestinal disease; for the commonest mechanism for the loss of potassium, as indeed of sodium, from the body is escape of gastro-intestinal secretions, associated as a rule with interference with food intake. For example, Martin et al. (1951) found that 81% of patients suffering from potassium depletion had disease of the gastro-intestinal tract. Lans, Stein, and Meyer (1952) found a similar preponderance of gastro-intestinal disease in their series; they report analyses of different secretions, showing that the potassium concentration is usually distinctly higher than that of plasma (table II). From these analyses, and from the volumes of the various gastro-intestinal secretions given by Gamble (1947), the total daily secretion of potassium into the alimentary tract is of the order of 66 m.eq., or 2·6 g.—about as much as is found in a mixed diet. Reabsorption of this potassium may be impeded by ion-exchange resins in the hydrogen cycle given by mouth; these have on occasion led to significant potassium depletion (Dock and Frank 1950).

Although gastro-intestinal secretions usually contain more potassium that is found in plasma, they contain much less potassium than they do sodium, and it is not altogether easy to see why gastro-intestinal disease can cause deficits of potassium quite comparable in absolute magnitude to those of sodium. However, other factors come in to modify the expectation that more sodium would be lost than potassium. When gastric juice contributes largely to the total loss, the relatively low Na/K ratio in this particular secretion will be reflected in a relatively high potassium loss. When on the other hand the main loss is by diarrhœa, the ratio of K/Na in the stools is much higher than in pure gastro-intestinal secretions. In the 6 infants studied by Darrow (1946), the loss of sodium in the stools often exceeded that of potassium when the stools were watery, but when the water content of the stools dwindled the loss of potassium exceeded that of sodium. Normal stools contain more than twice as much potassium as sodium (Shohl 1939); and when urine is introduced into the colon, and retained for three hours, the amount and concentrapotassium depletion could be worked out on these lines, but the normal and the diurnal variability of potassium excretion, and the effect of concurrent sodium depletion, present obvious difficulties If these can be surmounted, such a test would be of value in the difficult group of patients with potassium depletion and a normal serum level of potassium

* The second Goulstonian lecture for 1953, delivered before the Royal College of Physicians on Jan. 15.

The Pragmatic Sanction

As the sands run out towards the end of my attempt to portray body-fluid depletion, I enjoy a drowning man's vision of many sins of omission I have scarcely mentioned the influence of hormones on electrolyte distribution, the effect of metabolic activity in promoting electrolyte shifts, and the special problems of infancy yet all these are matters of the greatest importance My extenuation must be that in covering so vast a field I have been driven to a base empiricism, in that I have had to set therapeutic recommendations on a rickety foundation of half-truths My consolation is that the practical application of these methods, however insecurely founded they may be in theory, has often produced good results This pragmatic sanction, if one may call it so, is no justification for complacency, for the therapeutic successes are considerably overshadowed, not indeed by utter failures, but by unsolved and challenging problems, such as the low-salt syndrome associated with œdema, or the effects of potassium loss on cellular function

to rapid deposition of glycogen when insulin and glucose are given (Keys 1938). Retention of potassium is easily demonstrable during recovery from potassium depletion (Nabarro et al. 1952a), but does not of course afford a rapid assessment of the severity of depletion. Determination of the potassium content of muscle obtained at biopsy (Mudge and Vislocky 1949) likewise gives information of value but not of immediate clinical applicability. The potassium content of red blood-cells may not always be representative of that of tissue cells (Eliel et al. 1950); in moderate experimental potassium depletion, the potassium concentration in erythrocytes did not change appreciably (Black and Milne 1952). Determination of exchangeable potassium in the body with K^{42} may become the basis of a clinical test for potassium depletion, but the method has not yet been sufficiently explored. There is some evidence that the urinary output of potassium after a standard oral dose of potassium salts is related to the existing potassium household, and may thus be used as a clinical measure of potassium depletion. In the meantime, I would draw your attention to the more fundamental problem of assessing to what extent the multifarious clinical symptoms which have been described in association with potassium depletion can in fact be fairly ascribed to this particular biochemical distortion.

Symptoms Caused by Potassium Depletion

Muscular weakness and paralysis seem to be generally related to the serum-potassium level rather than to "global" potassium depletion; this is most clearly seen in periodic paralysis, in which a shift of potassium into the cells brings on an attack, without any net loss of potassium from the body (Danowski et al. 1948). Even here, however, the relationship is not strict, for Allott and McArdle (1938) point out that paralysis may be absent at levels of serum-potassium lower than those associated with attacks in other patients. The electrocardiographic changes seem also to be related to the serum-potassium level rather than to the total potassium deficiency in the body (Darrow and Pratt 1950). On the other hand, complete or partial atony of the smooth muscle of the bowel has been attributed to depletion of intracellular potassium, and this has even been adduced as a cause of paralytic ileus (Streeten and Ward-McQuaid 1952). The argument here does not seem completely rigid, at least in the experimental work quoted (Streeten and Vaughan Williams 1952); for the method used to deplete intracellular potassium would be associated with entry of sodium into the cells, and this might be the more important change. It has been shown that various enzyme actions are inhibited by sodium and potentiated by potassium (Cannon 1952), making it difficult to assign special importance to either ion when there is a reciprocal shift of both. Besides, the low intracellular potassium observed could be a sequel rather than a cause of paralytic ileus. Eliel, Pearson, and Rawson (1950), in patients after operation, have demonstrated potassium depletion, and they describe in association with this a formidable list of symptoms—"apathy, lethargy, nervousness and irritability, muscular weakness, abdominal distension and occasional ileus, occasional confusion, disorientation, delirium, muscular twitching and tetany, electrocardiographic changes and occasional arrhythmias and œdema." Other workers have made similar claims in other clinical contexts, but the account given by Eliel et al. may be taken as representative.

It will at once be noted that many of these symptoms are those with which we are familiar in any severe illness. In view of the ease with which potassium escapes from cells under abnormal conditions, we cannot dismiss out of hand the hypothesis that intracellular potassium depletion produces these striking effects. It seems just as reasonable, however, to suppose that potassium loss from cells is only one facet of a general biochemical distortion, and not necessarily the most important. These conflicting views cannot be critically tested in patients, for the conditions which cause clinical potassium depletion also cause loss or imbalance of other electrolytes. Even the amelioration of symptoms with repair of an intracellular potassium deficit is not absolutely certain evidence that these symptoms were due to the deficit, for potassium salts will modify the anion balance of the body as well as supply potassium to cells. The complications inherent in clinical studies can sometimes be evaded in part by an experimental approach, in which a depletion of the substance under consideration is established in normal subjects. This experimental method has in turn its own limitations. It cannot be carried *à outrance*, except in animals, and these cannot be used in a study partly designed to assess the significance of human symptoms. The purity of the depletion induced, which is the great virtue of experimental work on electrolytes, may also be a drawback, in that we lose contact with those synergisms of ion depletion which may be the essence of an actual clinical situation. Finally the means employed to induce a "pure" depletion may involve extensive juggling with food and way of life in general, so that the subjects are well aware of what is going on, and symptoms may sprout too luxuriantly on this conditioned soil.

Apart from these general limitations of the experimental method, its application to potassium depletion has been beset by the special difficulty that almost all natural foods are rich in potassium, and a really "low-potassium" diet must also be a rather strange one. For small animals, synthetic diets can and have been used to provide a balanced food intake; but the quantities needed for man would be very costly. An electrolyte-free diet of good calorie content is indeed available in the glucose/arachis-oil mixture devised for the maintenance of patients with anuria; but this diet is also protein-free, a disadvantage when tissue breakdown is to be avoided as far as possible. The introduction of exchange resins has made it possible to remove potassium from foods or from the alimentary tract; this method has been used in two recent experimental studies (Black and Milne 1952, Fourman and Ainley-Walker 1952). Milne and I used a resin in the sodium cycle, and passed 3 litres of milk through it each day, giving us a diet adequate in calories and protein, very low in potassium, and rather high in sodium. Fourman used a resin in the hydrogen cycle, so that the potassium withdrawn from the body

A, aureomycin, C, chloramphenicol, P, penicillin, S, streptomycin T, terramycin

have to be attacked is usually not clear, but the criteria of infection and cure are definite and the same in all cases—namely, the presence or absence of clinical symptoms and signs, and the presence or absence of exudate and micro-organisms in the urine

Of the 17 patients treated (tables I and II) 15 were females The ages ranged from 17 to 72 (average 49)

Each case was considered individually when the sensitivity of the organism was known, and the antibiotic thought to be most suitable was administered six-hourly The five-day period adopted at first was found to be unnecessarily long in some cases, and administration of the antibiotic was cut short twenty-four hours after a specimen of urine was apparently sterile

Terramycin, chloramphenicol, and aureomycin were given by mouth, and penicillin and streptomycin by injection

Bacteriological Examination of Urine

Catheter specimens of urine were examined in all the women, and mid-stream specimens in the men The urine was examined at least twice before treatment was started (In a few cases a longer period of observation without treatment was possible) The urine was examined six hours after the first dose and daily thereafter Follow-up specimens were examined fifteen days after therapy and again some months later

Bacteriological examination of each specimen included microscopy of wet and stained preparations from the centrifuged deposit All the specimens were examined microscopically and culturally within twenty minutes of sampling, and the number of organisms present was estimated by a plate-count of the fresh uncentrifuged specimen (Dick and Marwick 1953)

The effect of treatment on the number of organisms present in the urine and on the amount of exudate is shown in table III

Determination of Sensitivity and Assay

The centrifuged deposit was used to inoculate plates for a screen sensitivity determination (Gould and Bowie 1952, Bowie and Gould 1952), and diagnostic plates were incubated aerobically and anaerobically It was usually possible to identify the species of bacteria, and to determine their sensitivity to the antibiotics, within twenty-four hours, in most cases their sensitivity could be determined satisfactorily enough for calculation of the dose (see below) On subculture further biological identification was made if necessary, and confirmatory sensitivity tests were made with uniform standard inocula The sensitivity of each organism to all the antibiotics used was determined at each isolation so as to discover whether there was any change of sensitivity to the antibiotic in use or to any of the others

The supernatant urine was used for assay where appropriate In all the cases the agar diffusion method (Heatley 1944) was carried out in parallel with the serial tube dilution method using both a standard test organism and the infecting pathogen of the particular case under examination (Mackie and McCartney 1950) In cases where the dosage of antibiotic was very small and the expected concentrations in the urine were about 1 0 µg per ml or less, a turbidimetric method of assay was also employed (McMahan 1944)

Calculation of Dose of Antibiotic

The excretion-rates of the different antibiotics vary widely Almost all the penicillin administered can be recovered in the urine, whereas only a small percentage of biologically active chloramphenicol is recoverable (Glazko et al 1950) Previous estimates of these excretion-rates have been made by different methods, and it seemed advisable to carry out a pilot experiment on a series of people to ascertain what proportion of the antibiotics we intended to use would be found in the urine with our particular methods of assay

A group of students and a group of patients, with healthy renal tracts, were selected and given various amounts of antibiotics by different routes, the body weight and the intake and output of water were measured

TABLE III—EFFECT OF ANTIBIOTIC ON NUMBERS OF BACTERIA AND PRESENCE OF EXUDATE IN URINE

to rapid deposition of glycogen when insulin and glucose are given (Keys 1938). Retention of potassium is easily demonstrable during recovery from potassium depletion (Nabarro et al. 1952a), but does not of course afford a rapid assessment of the severity of depletion. Determination of the potassium content of muscle obtained at biopsy (Mudge and Vislocky 1949) likewise gives information of value but not of immediate clinical applicability. The potassium content of red blood-cells may not always be representative of that of tissue cells (Eliel et al. 1950); in moderate experimental potassium depletion, the potassium concentration in erythrocytes did not change appreciably (Black and Milne 1952). Determination of exchangeable potassium in the body with K^{42} may become the basis of a clinical test for potassium depletion, but the method has not yet been sufficiently explored. There is some evidence that the urinary output of potassium after a standard oral dose of potassium salts is related to the existing potassium household, and may thus be used as a clinical measure of potassium depletion. In the meantime, I would draw your attention to the more fundamental problem of assessing to what extent the multifarious clinical symptoms which have been described in association with potassium depletion can in fact be fairly ascribed to this particular biochemical distortion.

Symptoms Caused by Potassium Depletion

Muscular weakness and paralysis seem to be generally related to the serum-potassium level rather than to "global" potassium depletion; this is most clearly seen in periodic paralysis, in which a shift of potassium into the cells brings on an attack, without any net loss of potassium from the body (Danowski et al. 1948). Even here, however, the relationship is not strict, for Allott and McArdle (1938) point out that paralysis may be absent at levels of serum-potassium lower than those associated with attacks in other patients. The electrocardiographic changes seem also to be related to the serum-potassium level rather than to the total potassium deficiency in the body (Darrow and Pratt 1950). On the other hand, complete or partial atony of the smooth muscle of the bowel has been attributed to depletion of intracellular potassium, and this has even been adduced as a cause of paralytic ileus (Streeten and Ward-McQuaid 1952). The argument here does not seem completely rigid, at least in the experimental work quoted (Streeten and Vaughan Williams 1952); for the method used to deplete intracellular potassium would be associated with entry of sodium into the cells, and this might be the more important change. It has been shown that various enzyme actions are inhibited by sodium and potentiated by potassium (Cannon 1952), making it difficult to assign special importance to either ion when there is a reciprocal shift of both. Besides, the low intracellular potassium observed could be a sequel rather than a cause of paralytic ileus. Eliel, Pearson, and Rawson (1950), in patients after operation, have demonstrated potassium depletion, and they describe in association with this a formidable list of symptoms—"apathy, lethargy, nervousness and irritability, muscular weakness, abdominal distension and occasional ileus, occasional confusion, disorientation, delirium, muscular twitching and tetany, electrocardiographic changes and occasional arrhythmias and œdema." Other workers have made similar claims in other clinical contexts, but the account given by Eliel et al. may be taken as representative.

It will at once be noted that many of these symptoms are those with which we are familiar in any severe illness. In view of the ease with which potassium escapes from cells under abnormal conditions, we cannot dismiss out of hand the hypothesis that intracellular potassium depletion produces these striking effects. It seems just as reasonable, however, to suppose that potassium loss from cells is only one facet of a general biochemical distortion, and not necessarily the most important. These conflicting views cannot be critically tested in patients, for the conditions which cause clinical potassium depletion also cause loss or imbalance of other electrolytes. Even the amelioration of symptoms with repair of an intracellular potassium deficit is not absolutely certain evidence that these symptoms were due to the deficit, for potassium salts will modify the anion balance of the body as well as supply potassium to cells. The complications inherent in clinical studies can sometimes be evaded in part by an experimental approach, in which a depletion of the substance under consideration is established in normal subjects. This experimental method has in turn its own limitations. It cannot be carried *à outrance*, except in animals, and these cannot be used in a study partly designed to assess the significance of human symptoms. The purity of the depletion induced, which is the great virtue of experimental work on electrolytes, may also be a drawback, in that we lose contact with those synergisms of ion depletion which may be the essence of an actual clinical situation. Finally the means employed to induce a "pure" depletion may involve extensive juggling with food and way of life in general, so that the subjects are well aware of what is going on, and symptoms may sprout too luxuriantly on this conditioned soil.

Apart from these general limitations of the experimental method, its application to potassium depletion has been beset by the special difficulty that almost all natural foods are rich in potassium, and a really "low-potassium" diet must also be a rather strange one. For small animals, synthetic diets can and have been used to provide a balanced food intake; but the quantities needed for man would be very costly. An electrolyte-free diet of good calorie content is indeed available in the glucose/arachis-oil mixture devised for the maintenance of patients with anuria; but this diet is also protein-free, a disadvantage when tissue breakdown is to be avoided as far as possible. The introduction of exchange resins has made it possible to remove potassium from foods or from the alimentary tract; this method has been used in two recent experimental studies (Black and Milne 1952, Fourman and Ainley-Walker 1952). Milne and I used a resin in the sodium cycle, and passed 3 litres of milk through it each day, giving us a diet adequate in calories and protein, very low in potassium, and rather high in sodium. Fourman used a resin in the hydrogen cycle, so that the potassium withdrawn from the body

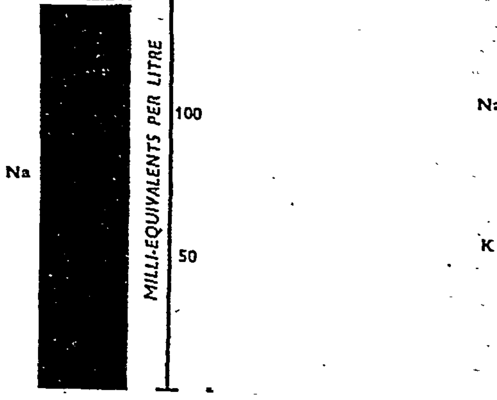

Fig. 3—Distribution of sodium and potassium in extracellular and intracellular fluid. Concentrations of electrolyte on the ordinate, volumes of the respective compartments on the abscissa, so that areas represent total amounts of electrolyte.

After the start of therapy the number of viable bacteria present in the urine decreased rapidly in most cases, especially those treated with streptomycin This decrease was accompanied by disappearance or considerable reduction in the amount of exudate (table III)

DISCUSSION

Bacteriological sterilisation of the urine was effected in most of the cases in the present series by a concentration of antibiotic in vivo approximating to that required to inhibit the infecting species in vitro The removal of the pathogens and the cessation of exudation were as rapid as would be expected if the usual therapeutic doses of antibiotic had been exhibited (Gould 1951), and the clinical response of the patients was at least as favourable (Cameron 1951)

The exhibition of antibiotics in a rational manner as described here has advantages which may be gained by the application of data obtained from the in-vitro tests at present made as a routine in hospital laboratories The most suitable antibiotic available against a particular pathogen may be given in a dosage which will cause no toxic effects in the patient and no side effects, such as gross upset of oral and intestinal flora Except for chloramphenicol, this rational dose is very low indeed. It may be possible to prevent the development of resistance to antibiotics by exposing the organisms to in-vivo concentrations closely related to their in vitro sensitivities

Certain species and groups of micro-organisms appear particularly liable to become resistant to antibiotics, and those possessing the rapid one-step streptomycin pattern of resistance constitute a definite clinical problem

All the individuals in a bacterial population are sensitive not to one particular concentration of a drug but rather to a range of concentration, which may be narrow or wide according to the antibiotic and species concerned If this range of concentration is X–Y, only 1% of the bacterial population may be killed at X (bacteriostatic level) but 99 9% at Y (bactericidal level) It is the latter value which is generally given in sensitivity reports Probably the potential resistant variants are to be found among the individuals which persist at this concentration, but these cells will not become resistant and dominant until a higher and critical concentration of antibiotic is reached The aim in therapy should therefore be to subject the organism to a concentration that is related as closely as possible to Y, which is the in-vitro bactericidal level This was the aim in the cases treated in the present series

The organisms isolated before treatment, when grown in vitro, all showed a well-defined zone X–Y but could be induced to form resistant variants by exposure to concentrations of antibiotic greater than Y in each case This was readily done by using streptomycin, it is well known that this antibiotic will induce resistant variants in culture and in the body during treatment We think it highly significant that in the present series no antibiotic resistant organisms were isolated either during or after treatment, although exposure lasted at least five days, sometimes longer

We gained the impression that, when used in rational doses, streptomycin is no more likely to induce resistance than is any other antibiotic, and further that it is the most valuable antibiotic in most urinary-tract infections

The principle behind the exhibition of antibiotics in this rational manner may well be applicable to the treatment of infection in other parts of the body Advance along these lines will depend on further knowledge of the antibiotic levels attained in individual tissues under any particular scheme of dosage

SUMMARY

The in-vitro sensitivity has been used in calculating a rational dosage of antibiotic in cases of infection of the urinary tract

17 cases were treated with satisfactory clinical and bacteriological results

No development of resistance to any of the antibiotics resulted from this therapy, and the number of resistant replacement strains encountered was less than when "standard" doses of antibiotics are exhibited

If the dosage of antibiotic is based on the in vitro sensitivity of the infecting micro organism, it will often be much lower than the "standard" dosage There is reason to suppose that if no more than the lowest effective dose is used, the infecting organism is unlikely to become resistant to the antibiotic

We have pleasure in thanking Prof T J Mackie, Dr W D D Small, and Dr E C Fahmy for their encouragement and guidance throughout this work, Mr K Marwick and Mr K. D Mackenzie for their untiring technical assistance, and Sister E A Hunter, Sister I Fraser, Sister C Hodgson, Staff nurse M Brown, and the nurses of wards 28, 29, and 49 of the Royal Infirmary, Edinburgh, for their enthusiastic coöperation.

FROM time to time theories of the pathology of poliomyelitis have been brought forward based on the conception that the pathways of the cerebrospinal fluid (C S F) are intimately concerned in the transmission of the virus Thus Burrows (1931) has carefully correlated the symptoms of poliomyelitis with the post mortem appearances in a large number of cases As a result of his findings he has regarded the perivascular spaces of the central nervous system as akin to the lymphatic vessels elsewhere in the body, and has suggested that their involvement in poliomyelitis is the direct cause of the damage to the nerve cells

Field and Brierley (1948a) have shown that the behaviour of particles introduced into the cranial subarachnoid space of animals may be similar to that of the virus of poliomyelitis in man Theories as to the pathology of poliomyelitis based on this type of experimental work must of necessity assume that the virus behaves as an inert particle similar in all respects to the particles injected experimentally This assumption is obviously a large one and must constantly be borne in mind before any conclusions about the pathology of nervous disease are based on the behaviour of injected particles In the presence, however, of the great difficulties that beset the study of the artificially induced disease, there appears to be a place for this method of investigation in the search for a rational pathology and therapy for poliomyelitis

The observations made in the present investigation were based on the fate of particles introduced into the subarachnoid space of the newborn rat, which animal has weakness in a patient recovering from diabetic coma whose serum-potassium was 3·1 m.eq. per litre, but whose bicarbonate was only 20·2 m*M*. per litre. Potassium chloride was given by mouth, and the apathy and weakness disappeared in an hour or two: the serum-potassium rose to 5·6 m.eq., but the mild acidosis remained uncorrected. By contrast, I have seen a patient with pyloric stenosis, whose serum-potassium was only 2·1 m.eq. per litre, but he was alkalotic with a bicarbonate of 38·2 m*M*. per litre; there was no demonstrable muscular weakness. Allott and McArdle (1938) have already noted the absence of paralysis in a patient with pyloric stenosis, and a serum-potassium of only 2·0 m.eq. In further and more general support of my contention that potassium depletion is more likely to cause symptoms when associated with acidosis, perhaps I may quote the independent clinical experience of Smart (1952), who says: "It is unusual to see paralysis in cases of potassium deficiency, but when it does occur it is usually seen in patients who are recovering from diabetic coma, in subjects with renal lesions such as chronic nephritis, or so-called calcinosis, or, much more rarely, in subjects with sprue and in patients with Addison's disease who have received too much DOCA." All these are conditions likely to be associated with acidosis, with the apparent exception of treated Addison's disease. I hope that what I have later to say on the so-called "hypochloræmic alkalosis" of potassium depletion may explain this solitary departure from the predicted association of symptoms with acidosis. Although there are obvious risks in transferring in-vitro evidence to a clinical situation, it is perhaps pertinent to mention here that the effects of a low environmental concentration of potassium on neuromuscular irritability are increased by making the surrounding fluid more acid (Gellhorn 1928, Lehmann 1937).

The Rise in Bicarbonate

May I now invite your attention to the rise in serum-bicarbonate which accompanied potassium depletion in both our subjects, and disappeared when the depletion was repaired. Raised serum-bicarbonate in association with potassium depletion has been described clinically, in Cushing's syndrome (McQuarrie et al. 1937), and also after surgical operations (Eliel et al. 1950); with potassium therapy, the serum-bicarbonate level falls (Kepler et al. 1948). This raised bicarbonate has often been described as a "hypokalæmic metabolic alkalosis," but it is difficult to see why loss of a base from the body should lead to alkalosis. When a similar rise in serum-bicarbonate occurred in experimental potassium depletion, there was an obvious opportunity of analysing its mechanism against the background of available balance results. We can distinguish four mechanisms, not mutually exclusive, by which the rise in serum-bicarbonate could be produced:

(1) Respiratory acidosis.
(2) Renal conservation of base.
(3) Change in the acid-base composition of the diet.
(4) Transfer of base from cells to extracellular fluid, with replacement by hydrogen ions.

RESPIRATORY ACIDOSIS

In clinical potassium depletion, irregularity of respiration, with inadequate ventilation, has been described (Denton et al. 1951). Hypopnœa could in theory lead to a raised serum-bicarbonate, in which event the alveolar carbon-dioxide tension (pCO_2) would also be raised. This sequence was an unlikely one in our subjects, in view of the absence of general clinical symptoms, and we were able to show in one subject that the alveolar pCO_2 remained unchanged at the height of depletion. This indicates a calculated rise of plasma pH from 7·48 to 7·58, and establishes the presence of an alkalosis in extracellular fluid.

RENAL CONSERVATION OF BASE

Berliner et al. (1951) have shown that potassium and hydrogen ions compete for some component of the ion-exchange mechanism in the distal renal tubule, so that a diminished secretion of potassium might favour the elimination of hydrogen ions in the urine. The secretion over a period of a urine too acid for the body's metabolic needs would cause alkalosis, and they propose this as a mechanism for the "alkalosis" associated with clinical potassium depletion. There was in fact some evidence in our subjects that hydrogen-ion secretion was being favoured by diminished potassium secretion; for the output of (ammonia + titratable acidity) was negatively correlated with the potassium output, increasing even in the presence of E.C.F. alkalosis, which would be expected to decrease renal output of acid. This apparently disadvantageous change in renal behaviour was not, however, the main cause of the observed alkalosis, though it may have enhanced it in a minor degree; for the urine in the depletion periods was considerably less acid than in the control periods. It might still be argued that although the urine became less acid, it might nevertheless be prevented by the Berliner mechanism from becoming as alkaline as the changed metabolic needs of the body would dictate. We must now examine this possibility quantitatively.

CHANGE IN ACID-BASE COMPOSITION OF DIET

The conditions of the experiment introduce a complication into our treatment of this subject. Since potassium was almost entirely replaced by sodium in the depletion periods, we were forced to give supplements of sodium salts in the preliminary and after periods, if the sodium intake was to be constant. We did this with chloride alone in the first experiment, so that the chloride intake was considerably higher in the control and after periods than in the depletion period. In the second experiment, we modified this by giving chloride and bicarbonate in the proportions found in E.C.F., believing that such a mixture would be "biologically neutral." There was still, however, a substantial excess of chloride in the diet, in the control and after periods, so that in both experiments in the depletion period less fixed base (sodium plus potassium) was "covered" in the diet by chloride, and this might well favour alkalosis.

To examine this matter further, we have calculated the fixed base and chloride intake and output in the various periods. As the fixed acids other than chloride did not change in the diet, the difference between dietary fixed base and chloride is a measure of the alkalinising tendency of the diet, while the difference between output of fixed base and chloride indicates the extent to which the dietary change has been compensated by change in excretion. In subject 1, who had the sodium supplements entirely in the form of chloride, there was a very considerable excess of (fixed base minus chloride)

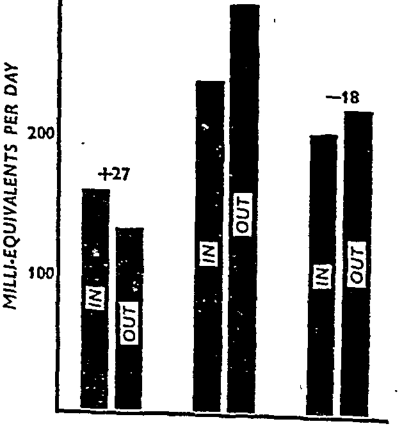

Fig. 5—Comparison of intake and output of "alkali" in preliminary, resin, and after-periods in subject 2. "Alkali" under the conditions of the experiment is given by Na + K – Cl.

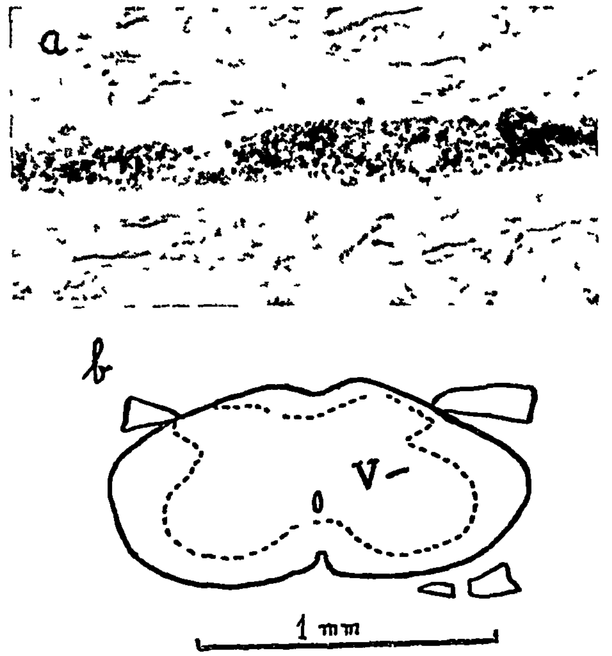

Fig 3—Transverse section of spinal cord of rat aged 21 days : *a*, carbon particles in perivascular space round small blood vessel (× 1250) , *b*, position of blood vessel (V) illustrated in *a*

the finding of Brierley (1950) that, under physiological conditions, particles can penetrate into the perivascular spaces To the perivascular spaces has been ascribed, by those workers who postulate a centrifugal direction of flow, the function of production or at least augmentation of the C S F More rarely the opposite view is taken that absorption takes place along these channels The results of the present experiments lend support to the view that these channels represent anatomical cul-de-sacs similar to those surrounding the emerging nerve-roots—backwaters in which there is a gentle eddy in both directions rather than a constant flow in one Their main function may be to act as fluid cushions intervening between the nerve cells and the contracting and expanding blood vessels of the brain and spinal cord

Burrows (1931) has regarded the pressure of the exudate in the perivascular spaces as the cause of the injury to and ultimate destruction of the anterior-horn cells in poliomyelitis The presence of such an exudate may lower the cushioning properties of the perivascular spaces and thus expose the nerve cells to the pressure changes produced by the passage of blood through the vessels That the presence of an abnormal substance in the perivascular spaces round the vessels in the region of the anterior horn may damage the anterior horn cells is shown by the work of Davis et al (1930), who found that iodised oil injected through the cisterna magna into the subarachnoid space of dogs eventually destroyed the anterior-horn cells The vulnerability of the anterior horn may be related to the rich vascularity of this region, for the greater the vascularity of a region of the cord the greater, presumably, is the area occupied by the perivascular spaces

The various situations in which particles injected into the subarachnoid space can be found may have some bearing on the stages of poliomyelitis in man The abdominal upset which often ushers in the illness may be due to the presence of the virus in the abdominal lymph glands, whether it reaches these from the intestines or from some other locus of infection The " meningitic " phase may be due to the presence of the virus in the subarachnoid space which it could reach along the pathway from lymph gland to subarachnoid cul de sac These subarachnoid cul de sacs occur along both cranial and spinal nerves and may collect exudate in poliomyelitis in the same way as they collected particles in the experiments on rats The presence of an exudate in this situation might be responsible for the occurrence, in this phase of symptoms such as neck rigidity and root pains due to irritation of the appropriate cranial and spinal nerves

The third or " paralytic " stage is, as is well known, associated with the presence of exudate in the perivascular spaces of the spinal cord It is interesting to note that particles injected into the subarachnoid space of rats were found within the subarachnoid cul de sacs round the emerging nerve roots a few minutes later, but their appearance within the perivascular spaces was delayed until 24–48 hours after the initial injection (Brierley 1950) It is tempting to conclude that the filling of the perivascular spaces depends on the blockage of the pathway of escape of the particles from the C S F via the subarachnoid cul de sacs into the prevertebral lymph glands The bearing which such a possibility has on this phase of the poliomyelitis cycle is self evident

THERAPY OF POLIOMYELITIS

The anatomical observations outlined here suggest that three stages can be distinguished in the fate of particles injected into the subarachnoid space of newborn rats (1) the formation of subarachnoid cuffs round the emerging nerve roots , (2) the filling of the prevertebral lymph glands , and (3) the appearance of particles in the perivascular spaces of the cord These stages appear to be so closely related to the phases of invasion by the virus in man that the question arises whether this fact can be used in treating poliomyelitis

The cellular exudate found in the perivascular spaces of the spinal cord in poliomyelitis may be (1) a simple exudate from the blood vessels, (2) due to a reaction in the perivascular spaces, or (3) an accumulation of cells derived from a generalised process in the subarachnoid space If, as Burrows (1931) has suggested, the destruction of the anterior horn cells is primarily due to mischief occurring in the perivascular spaces, then, irrespective of the origin of the exudate, the adequate drainage of the perivascular spaces appears to be of fundamental importance to the treatment of poliomyelitis

It is perhaps significant in relation to this proposition that repeated lumbar puncture has been widely advocated as a method of treatment The removal of C S F by lumbar puncture is one of the three methods by which it is possible to achieve a circulation of the fluid in the perivascular spaces The other methods by which a flow of the fluid in these spaces can be promoted are extreme exsanguination and the intravenous administration of hypertonic solutions Whereas extreme exsanguination is clearly impracticable, perhaps a method of treatment based upon the intravenous administration of hypertonic solutions has potentialities which have yet to be realised

The intravenous administration of a hypertonic solution promotes the circulation of the C S F in the perivascular spaces Hence the combination of this technique with the intrathecal injection of a therapeutic agent would enable that agent to reach the perivascular spaces

Whichever theory concerning the transmission of the virus of poliomyelitis is held, it is clear that such a method of administration must bring a therapeutic agent into closer contact with the virus, whether it be in the neurone or in the perivascular spaces, than any of the methods of therapy which depend on the agent reaching the virus via the blood-stream

The combination of the intravenous injection of hypertonic solutions with the intrathecal administration of antibiotic substances appears therefore to be high sodium intake of our experiments may have contributed to E.C.F. expansion and I.C.F. shrinkage. Our own experience would suggest that the clinical effects of an isosmotic reduction of I.C.F. are negligible, in interesting contrast to the great thirst and the definite malaise evoked by a comparable reduction in I.C.F. volume caused by primary water depletion, and so associated with hypertonicity (Black, McCance, and Young 1944).

Making Good the Deficit

It has to be emphasised that the potassium depletion induced in our experiments was moderate, and the clinical deductions which can be drawn directly from them are correspondingly limited. They suggest rather strongly, however, that potassium depletion of the order of 250–300 m.eq. is not likely to be a direct cause of symptoms, except when associated with acidosis. This conclusion cannot necessarily be extrapolated to depletions of the order of 1000 m.eq., such as arise from large and sustained losses of alimentary secretions; but a short note by Aikawa and Felts (1952) claims that in cortisone-induced potassium depletion "reduction of less than 30% in exchangeable potassium was not accompanied by clinical symptoms or signs of deficiency." On the other hand, large deficits of an important intracellular base would be expected to influence cell function unfavourably, and there is evidence from work on animals that potassium depletion may interfere with enzyme activity (Boyer et al. 1942), with glycogenesis (Gardner et al. 1950), and with the utilisation of dietary protein (Cannon et al. 1952). Cardiac and renal lesions have been found in potassium-depleted rats (Follis et al. 1942, Darrow 1944), and similar lesions have been reported in patients (Keye 1952). The abnormal electrocardiogram associated with potassium depletion on the basis of experiments on animals has often been demonstrated in patients, together with irregularities of cardiac action; and there is some evidence that potassium depletion increases cardiac susceptibility to the action of digitalis (Lown et al. 1952).

Perhaps the most convincing evidence of the actual clinical value of repairing a potassium deficit is the study of Govan and Darrow (1946), quoted previously, in which mortality in the same outbreak of gastro-enteritis was much less in the infants given potassium supplements. The balance of evidence seems to me quite clearly to favour the giving of potassium whenever there is good clinical and biochemical evidence of potassium deficiency. There is no real difficulty when the patient can take potassium salts by mouth, and a good case can be made out for giving potassium by this route to any patient with adequate renal function who is losing potassium in stools or urine, and who is not vomiting. Unfortunately, many patients with potassium depletion are unable to take or retain oral potassium, and in them the risks of potassium depletion must be balanced against the risks of parenteral potassium administration. There seems little doubt that a large deficiency of potassium can cause unpleasant symptoms, and even contribute to a fatal issue, but a moderate potassium depletion can probably be disregarded until potassium salts can be given by mouth. The risk of parenteral potassium administration is quite definite, and the danger of cardiac arrest depends on the serum level of potassium; a rise to 10 m.eq. per litre may be fatal. How is it to be avoided?

A potassium depletion must always have been actually demonstrated in the individual patient before potassium infusion is even considered; it is not right to give potassium infusions to patients after operation, for example, just because other postoperative patients have been judged to have a potassium depletion. Not only is a demonstrable potassium deficiency the only valid reason for giving parenteral potassium; it also lessens the toxicity of potassium. Potassium-depleted rats show increased resistance to potassium poisoning (Miller and Darrow 1940, Muntwyler 1950). Human evidence on this point is difficult to obtain, but the increase in serum-potassium after an oral dose of potassium is less in a potassium-depleted subject than in the same subject when normal (Black and Milne 1952). I have heard of one patient with a severe potassium depletion who had a pint of 2% potassium chloride (270 m.eq. per litre) given intravenously in less than three hours, without ill effect. I can only say that if anyone wanted to do this to me, I should insist on a severe potassium depletion beforehand.

Sodium and potassium depletion occur more often together than separately, and the coexistence of sodium depletion adds to the risks of giving potassium parenterally. With sodium depletion, the serum level of potassium is often high, in spite of a cellular potassium deficit, and the patient is that much nearer to a toxic serum level. Moreover, the renal excretion of potassium is interfered with in these patients, and the E.C.F. volume is smaller, so that added potassium will cause a greater concentration change. Perhaps I may repeat the suggestion made in the first lecture, that sodium replacement should be carried to the point of restoring circulatory and renal efficiency, before potassium is given parenterally. In more practical terms, the blood-pressure should be normal, "shock" or peripheral circulatory failure should have been corrected, and the urine volume should be adequate.

Since potassium toxicity is a matter of extracellular fluid concentration, the rate of infusion and the potassium concentration of the infused fluid are of first importance. Potassium solutions, either chloride, phosphate, or lactate, for general use should not contain more than 40 m.eq. of potassium per litre, and should not be given more rapidly than a litre in three hours. I am aware that more concentrated solutions have been given more rapidly without mishap by physicians and surgeons specially interested in potassium metabolism; but they know the hazards, and the night-nurse in a general ward does not. My conservatism in this matter is dictated by the belief that potassium therapy, if necessary intravenously, can be of great value in selected cases; and I do not want to see it discredited by accidents in the "routine administration" of potassium to patients who are not materially depleted of potassium. Just as with sodium, treatment which is appropriate to one patient may be mischievous and even dangerous in another.

In the first lecture, I discussed the evidence needed to establish the presence of sodium depletion. The position with regard to potassium is more difficult, in that we cannot determine practicably the concentration of potassium in the main body-reservoir of potassium, the I.C.F., as we can do so easily with sodium in plasma, which represents extracellular fluid. We have therefore to rely more on indirect evidence, such as a history of potassium loss, or more precisely of some condition likely to cause potassium loss; muscle weakness and electrocardiographic changes; and indirect biochemical evidence. A low serum level of potassium almost always implies a general potassium depletion, especially in the fasting patient; but a normal serum-potassium does not exclude potassium deficiency. An unexplained rise in the alkali reserve should make one consider potassium depletion.

When the serum level of potassium is normal, but potassium loss is likely from the history, a decision on potassium depletion is difficult. One approach is to correct sodium depletion, and repeat the serum-potassium estimation, giving potassium if the level has fallen. Black and Milne (1952) found that the urinary excretion of potassium after a standard dose was related to the initial deficit of potassium in the body. Some preliminary observations on normal people suggest that a test for

TABLE III—COMPARISON OF VITAMIN E AND CONTROL GROUPS ACCORDING TO PATIENT'S ASSESSMENT OF RESULT OF TREATMENT

Result	Vitamin E	Control	Total
Improved	8	6	14
No change	12	14	26
Deteriorated	0	1	1
Total	20	21	41

patient's individual average number of circuits was calculated The means of these individual averages were then computed in the two groups, and they are shown in table I to be quite close Similarly, for each patient the average duration of pain after stopping exercise was determined The mean value was shorter in the vitamin-E group but not significantly so The two groups do, however, differ significantly in the average time taken per circuit The vitamin-E group take, on the average, 5·6 seconds per circuit, against 6·5 seconds for the control group, the difference of 0·9 has a standard error of 0·3, and such a difference, or a larger one, would be expected to occur purely by chance only about once in fifty times Thus the random allocation has led to rather more of the initially brisker walkers being chosen for the vitamin-E than for the arachis oil treatment This means that any apparently marked effect of treatment in favour of vitamin E must be examined carefully to see whether it may have resulted from the initial disparity in walking speeds between the groups

The distribution of cases, as classified by the method of Boyd et al (1949), is shown in table II There is no conspicuous difference between the groups, but again the vitamin-E group contains a slightly higher proportion (55%) of grade-II (less severe) cases than the control group (43%)

TABLE IV—INCREASE IN AVERAGE NUMBER OF CIRCUITS DURING WHOLE TREATMENT PERIOD COMPARED WITH PRE TREATMENT PERIOD

Group	No of cases	Average no of circuits		Mean increase ± standard error
		Pre treatment	During treatment	
Vitamin E	20	19·02	20·66	1·64 ± 0·86
Control	21	18·12	19·04	0·92 ± 0·84
			Difference	0·72 ± 1·20

RESULTS OF TREATMENT

Various measures of the improvement shown by the two groups during or after the period of treatment are summarised in tables III–VII The patients' own assessments of the effect of treatment are tabulated in table III There is clearly no appreciable difference between the two groups These subjective assessments of the patients are more optimistic than the objective ones presented in the following tables Throughout the period of treatment the observers could not distinguish between patients given vitamin E and those given arachis oil either by the patients' statements or by clinical examination

For each patient the average number of circuits walked in the pre treatment period (the measure used in table I) was subtracted from the average number walked during the whole of the treatment period This difference provides a measure of the patient's improvement in exercise tolerance during the treatment period Table IV shows the mean increase that took place in each of the groups, with its standard error It will be seen that in neither group was there any substantial improvement in performance The vitamin-E group shows a slightly greater increase (0·72 circuits) compared with the control group, but the difference is not significant

Very similar results are shown in table V, where the pre-treatment averages are contrasted with those prevailing during the last month of treatment The vitamin E group again shows a slight, but non significant, improvement over the control group The control group here was reduced to 19 patients because 2 of the 21 did not visit the clinic during this part of the treatment period

The possibility that the treatment took effect after the conclusion of the three months' treatment is examined in table VI Here, for each patient, the pre treatment average number of circuits is subtracted from the average number achieved during the three months following the end of treatment The post treatment visits were rather irregular, but all the patients except 1 in each group had at least one visit during this period Once again the effect shown is small, and there is no significant difference between the groups

TABLE V—INCREASE IN AVERAGE NUMBER OF CIRCUITS DURING LAST MONTH OF TREATMENT COMPARED WITH PRE TREATMENT PERIOD

Group	No of cases	Average no of circuits		Mean increase ± standard error
		Pre treatment	Last month of treatment	
Vitamin E	20	19·02	20·86	1·84 ± 0·96
Control	19	17·81	19·03	1·22 ± 0·99
			Difference	0·62 ± 1·38

The duration of pain that was experienced by each patient after his exercise tolerance test is analysed in table VII The average duration experienced by the patient in the pre-treatment period (as used in table I) was subtracted from the corresponding average observed during the treatment period The difference between these two values was then expressed as a percentage of the pre treatment values to reveal the relative improvement (or deterioration) in the patient For instance, in the pre-treatment period a patient may, on the average of his observations, have experienced pain for 40 seconds During treatment his average duration may have become 30 seconds, and this is represented by an improvement of 10 seconds in 40 (25%) The means, over the two groups of these individual percentage changes are given in table VII In the whole period of treatment the vitamin E group shows a small and non significant reduction of 9·7% in duration of pain, while the control group shows a small and non-significant increase of 8·3% The difference between these two values (18%) has a standard error of 7·0% and is therefore technically significant

It is essential to determine whether this significant result in favour of the vitamin-E group is due merely to the disparity between the groups which has been noted earlier Analysis within the two groups shows that it was patients who took the longest time over a circuit in the pre treatment period who tended also, on the average, to show subsequently the least improvement

TABLE VI—INCREASE IN AVERAGE NUMBER OF CIRCUITS DURING FIRST THREE MONTHS AFTER TREATMENT COMPARED WITH PRE TREATMENT PERIOD

Group	No of cases	Average no of circuits		Mean increase ± standard error
		Pre treatment	First three months after treatment	
Vitamin E	19	18·88	19·85	0·97 ± 1·01
Control	20	18·32	19·82	1·50 ± 0·99
			Difference	−0·53 ± 1·41

DOSAGE OF ANTIBIOTICS

RELATION BETWEEN THE IN-VITRO AND IN-VIVO CONCENTRATIONS EFFECTIVE IN URINARY-TRACT INFECTIONS

The in-vitro bacteriostatic or bactericidal concentration of an antibiotic for any bacterial species can be readily ascertained in the laboratory. But, though the results are of recognised value in selecting the most suitable antibiotic for treatment, they are not used in deciding the dosage. This is largely because little is known about the concentration of the various antibiotics in the different tissues of the body during treatment. Reliance is placed instead on "standard" serum levels, and, according to these levels "standard" dosage schedules have been devised with reference to excretion-rates. The infecting micro-organisms are classified as sensitive or otherwise in relation to the expected serum levels of antibiotic resulting from these "standard" doses.

No attempt has yet been made to effect in vivo exactly the same concentration as is known to inhibit the micro-organism in vitro.

This paper records an attempt to correlate the therapeutic dosage of antibiotics, and the resulting in-vivo concentrations, with the results of in-vitro sensitivity estimations.

METHODS

Selection of Cases and Administration of Antibiotics

Infections of the urinary tract were selected for the trials because they are common, the collection of satisfactory specimens is relatively easy, and the cases are generally amenable to treatment. In uncomplicated cases the invading micro-organisms seem to be relatively accessible to antibiotics given systemically; and, compared with infections such as endocarditis, therapeutic results are more closely related to in-vitro sensitivity. The particular site at which the micro-organisms

in the duration of pain in spite of the greater effort (Hamilton and Wilson 1952) If the treatment were beneficial, a definite *improvement in the vitamin-E* group over the controls should have been revealed by this method of performing exercise-tolerance tests

Patients with intermittent claudication of all degrees of severity have been studied, though Boyd (1951) has stated that only the less seriously affected (his grades I and II) respond to vitamin E With the more severe exercise of walking over steps the pain, once developed, persists in all patients, and with this test none fall into Boyd's grade I Our grades II and III thus include several cases that would have fallen into lower groups if the tests had been performed by walking on the level There is *thus* no doubt that the series contained in both control and treated groups many of the milder cases reputed to respond to vitamin E

These observations and considerations indicate clearly that vitamin E is of no appreciable benefit to patients with intermittent claudication The previous favourable reports have not included details of any adequate control studies In investigations of intermittent claudication reliance has always to be placed on an end-point determined by the patient's assessment of his pain It has previously been demonstrated that this may be modified by any action involving therapeutic suggestion In these circumstances the trial of any drug must be most rigorously controlled Frequent exercise-tolerance tests are essential before, during, and after the period of treatment, preferably at fortnightly intervals Finally, the trial should be conducted on the "double blind" principle, and before any drug is claimed to be effective it must be shown to be so when both patient and observer are unaware of the nature of the treatment

SUMMARY

The effect of natural vitamin E in intermittent claudication was investigated in 41 patients, divided at random into control and treatment groups The controls received capsules containing arachis oil, and the treatment group received capsules identical in appearance but containing vitamin E The daily dose was 450 I U, the equivalent of 450 mg of tocopherol, and was continued for twelve weeks

Until the whole trial was completed the clinical observers (and the patients) were unaware of the treatment given in any particular case The assessment of the effect of therapy was based on the patient's opinion, the clinical examination, and the results of exercise tolerance tests

No appreciable difference was found between the response of the two groups

It is concluded that vitamin E is of no value in the treatment of intermittent claudication

This investigation was made at the suggestion of the Medical Research Council, who arranged the supplies of vitamin E We should like to thank Prof G W Pickering and Prof E J Wayne for helpful advice and criticism We are grateful to them and to the physicians and surgeons of St Mary's Hospital, London, and the Royal Infirmary, Sheffield, for access to patients under their care We should also like to thank Dr A M Adelstein for assistance in the statistical analysis

Roelsen (1939) demonstrated that in emphysematous patients, more than in normal people, the composition of the expired air varied with the volume expired His findings have been confirmed by Marshall, Bates, and Christie (1952), who interpret them as evidence of poor spatial correlation between ventilation and perfusion in emphysematous lungs The possibility thus arises of using fractional analysis of expired air as a clinical test for emphysema However, because of the labour entailed by the analysis of multiple samples of gas, the methods of the previous workers are hardly suitable for routine clinical use

We describe here the use of a commercial analyser for continuous recording of the carbon dioxide content of respired air The abnormal pattern is easily recognised and, since repeated observations are conveniently made, the method lends itself to a study of the influence of relevant factors A somewhat similar procedure, using a specially constructed instrument, was described by Dubois et al (1952) who were, however, concerned with normal rather than pathological respiration

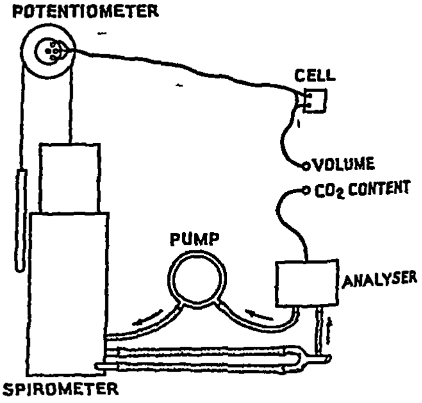

Fig 1—Arrangement of spirometer and carbon dioxide analyser

METHODS

The patient breathes into a Benedict spirometer fitted with a carbon dioxide absorber Attached to the wheel of the spirometer is a potentiometer which gives an electrical record of the amount of air in the bell at any moment A side tube to the mouthpiece is connected by a short length of rubber tubing to the analyser* Air is drawn, at a rate of about 30 ml per second, from the mouthpiece through the analyser by a small electric pump and is then returned to the spirometer bell In this way the respired gases are continuously sampled without disturbing the registration of their volume (fig 1)

The analyser's electrical system uses amplitude modulation of a 6 cycle-per sec carrier, rectified and smoothed to give a response time of several seconds As a much quicker response was required, the unrectified signal was taken out and rectified, without smoothing, by an external circuit With this arrangement the response to sudden changes of gas mixture is complete in about one third of a second

Sometimes, in addition, intrathoracic pressure and trunk expansion were recorded by the method of Dornhorst and Leathart (1952) and the concentration of the antibiotic in the serum and urine was estimated six hours after administration. The results (table IV) gave us a six-hourly percentage recovery-rate for each antibiotic. (The possible cumulative effect of repeated doses was ignored at this stage.) Since the in-vitro sensitivity was determined in each case by the same technique and with the same material, excretion-rates and expressions of sensitivity are correlated as far as possible. In calculating the dose of antibiotic for each patient we aimed at a *mean antibiotic level in the urine* equivalent to the level which inhibited the infecting organism in vitro. In view of the known variation in the excretion of antibiotics, confirmed by these experiments, and the known experimental error of our in-vitro tests (+25%), we decided to use a "dose-enhancing factor" to cover all variables, in the hope that this would ensure an antibiotic level in the urine at least as great as the in-vitro bactericidal concentration. The dose was calculated by multiplying the sensitivity expressed in µg. per ml. (table I) by the average six-hourly volume of urine passed during the period of observation; the product was multiplied by the reciprocal of the six-hourly excretion-rate of the antibiotic (table IV) to allow for the proportion of antibiotic not excreted in the urine. Finally this value was multiplied by our dose-enhancing factor.

---

* Infra Red Development Co Ltd Type S C

The calculation of the dose of streptomycin in case 1 (table I) is given as an example. The sensitivity of the coliform organism in this case was 0·2 µg. per ml., the urinary output was 200 ml. in six hours, the excretion-rate of streptomycin was 20% (table IV), and the dose-enhancing factor adopted in this case was 5. The six-hourly dose of antibiotic was therefore

$$\left(0{\cdot}2 \times 200 \times \frac{100 \times 5}{20}\right) \mu\text{g.} = 1000\,\mu\text{g. or } 1\text{ mg.}$$

TABLE IV—6-HOURLY EXCRETION OF ANTIBIOTIC

Antibiotic	Recovery of oral dose (%)		
	Students	Patients	Mean
Penicillin	66–92	70–84	80
Streptomycin ..	18–24	16–25	20
Chloramphenicol ..	2·6–4·6	1·2–4·8	3·4
Aureomycin ..	22–33	20–25	27
Terramycin ..	4·4–10·5	1·5–5·3	7·5

Table V shows the dose-enhancing factor used, and the factor actually obtained experimentally, in each case. The latter value was about half the estimate in most cases; hence the factor might well be reduced to 2·5.

RESULTS

The immediate result of treatment in 14 of the 17 cases (table I) was sterilisation of the urine. Of the remaining 3 patients case 7 had a staphylococcus originally present in small numbers, which remained after the first course of aureomycin; case 10's infection was of multiple species and long standing, in the presence of gross bladder disease making modification of the infection all that could be hoped for; and case 15 became infected with proteus during therapy, after removal of the original infecting species.

Of the 14 patients in whom the infection was cleared by the first course of antibiotic 5 became infected after therapy had stopped (table II), 4 with new infecting species and 1 with the original pathogen. Of these 5 patients 4 were successfully treated with a subsequent course of antibiotic, and the 5th passed out of our hands before completing a second course. The over-all result was that the urine in 14 of the original cases became sterile and remained sterile during the follow-up period, which varied from one to six months.

We think it of profound significance that in no case did antibiotic resistance develop in any of the original species either during therapy or after therapy, even when this was prolonged, as in case 12. Some species causing new infections did, however, show resistance to the antibiotic first exhibited.

TABLE V—RATIO OF URINE CONCENTRATION TO IN-VITRO INHIBITORY CONCENTRATION

12	10	4
15	10	6

Subcultures of every organism isolated in this series of cases were kept for various investigations, such as fuller biological identification, at a later date. Those organisms isolated on the first bacteriological examination in each case, and several isolated during treatment, have all proved capable of developing resistance in vitro to the antibiotic to which they had been exposed in vivo. Further, resistance to the antibiotics exhibited did develop in 3 of the cases in this series when the usually accepted "standard" doses were given outside these trials (table VI).

In the cases infected with a single bacterial species the use of a single antibiotic was effective in sterilising the urine. This was accompanied by clinical improvement or cure (cases 1, 3, 6, 8, 11, 13, 14, 16, and 17).

The use of two or more antibiotics simultaneously is indicated and is effective in urinary infections where more than one species of micro-organism is present and in-vitro tests indicate that no single agent will cover all the pathogens. A combination is also indicated and is effective when two antibiotics are observed to act synergically in vitro against a single bacterial species, and the use of the combination allows appreciably smaller quantities of one or both antibiotics to be exhibited. In case 13 it was found possible to use a twentieth of the usual dose of chloramphenicol by combining it with a very small dose of aureomycin.

TABLE VI—EFFECT OF STANDARD DOSES OF ANTIBIOTICS IN RAISING THE RESISTANCE OF ORGANISMS IN URINE OF PATIENTS IN THIS SERIES

Case no.	Sensitivity before antibiotic (µg. per ml.)					Therapy	Sensitivity after antibiotic (µg. per ml.)

A, aureomycin; C, chloramphenicol; P, penicillin; S, streptomycin; T, terramycin.

about 0 5% during a forced expiration of 1–2 litres (fig 2). in ten patients, considered on other grounds to have emphysema, the climb ranged from 2 to 4%, although the greatest volume expired was usually curtailed (fig 3) The continuous records bring out further differences Normally, as was also found by Dubois et al (1952), the rate of climb is virtually independent of the rate of expiration , hence during a long expiration the record is straight and gently sloping Moreover, the carbon dioxide content of the expired air is almost independent of its volume, though of course inversely related to the size of preceding breaths In the emphysematous patient the rate of climb is directly related to the rate of expiration and, as this is usually decreasing, the record is curved, while, since the carbon dioxide content increases with the volume expired, a larger expiration carries the content well above that of adjoining breaths One can appreciate how the patient's expired air will, during moderate ventilation, be far from representative of his mean aveolar air, and how an abnormally large discrepancy between the gas tensions in the expired air and in the arterial blood can develop

Normal patterns were obtained from a patient, aged 73, with early hypertensive cardiac failure, and from two young patients with uncomplicated asthma The latter finding agrees with the conclusions of Bates (1952) that ventilation-perfusion relationships were as a rule normal in asthma

Patients with gross chest disease (bronchiectasis, &c) but without overt emphysema gave patterns of intermediate climb (1–1 5%) The significance of these must await further experience

The effect of a bronchodilator spray (1% isopropyl-adrenaline) was examined in all the patients Many claimed easing of breathing, and in two cases bronchodilatation was demonstrated by changes in the intrathoracic pressure-record *In no instance was improvement in the abnormal carbon dioxide pattern produced* indeed the climb was sometimes increased, probably because the patient emptied his chest further after the spray In three cases parenteral adrenaline was also without effect on the pattern

One patient with asthma and early emphysema was studied during and after a period of exacerbation of his asthma Although the intrathoracic pressure records showed a great difference in the state of the bronchioles, there was little change in his abnormal carbon dioxide pattern (fig 4)

DISCUSSION

The procedure described is easy to apply with little disturbance even to severely dyspnœic patients It yields evidence that is sometimes unequivocal, since patterns such as that shown in fig 3 must imply disturbed ventilation-perfusion relationships It is still uncertain if this type of disturbance occurs with significant frequency with normal expired air patterns Although this is in principle possible if all regions are emptied simultaneously, some sequential emptying is very likely on mechanical grounds Further experience is therefore needed before it can be asserted that the test can exclude as well as demonstrate the presence of emphysema

The stability of the pattern in face of spontaneous and induced changes in bronchiolar resistance is unexpected on current views of the mechanism of its production However, its comparative stability enhances confidence in its diagnostic significance

SUMMARY

A method of automatic registration of volume and fractional analysis of carbon dioxide content of expired air is described

The occurrence of an abnormal pattern of expired-air composition with emphysema is confirmed

The abnormal pattern persists with induced or spontaneous changes in bronchiolar constriction

The procedure forms a practical clinical test for the presence of one important form of pulmonary dysfunction

AN OUTBREAK OF BENIGN MENINGO-ENCEPHALITIS

ISOLATION OF COXSACKIE VIRUS

J F Galpine

OF THE VIRUS REFERENCE LABORATORY, COLINDALE

During the summer of 1951 an unusual number of patients with symptoms and signs of mild neurotropic illness were admitted to a Coventry hospital with a diagnosis of "meningitis" or of non-paralytic poliomyelitis The admission to hospital during the same period of a few patients with paralytic poliomyelitis, the high incidence of this infection in recent years, and the knowledge that not all cases develop paralysis had induced a bias in favour of the diagnosis of non paralytic poliomyelitis Later the high proportion of non paralytic patients raised doubts about the rôle of poliomyelitis virus, and virus investigations were undertaken

Wallgren (1925) described an apparently identical condition, which he called acute epidemic aseptic meningitis, considering it to be distinct from poliomyelitis because not all the reported outbreaks were associated with poliomyelitis As a result of investigations since then it is now recognised that this clinical syndrome may occur in other known and suspected virus infections, including benign lymphocytic choriomeningitis, mumps and glandular fever, and in leptospiral infection (MacCallum 1949) Epidemiological studies by Thomson (1952) showed that in 1950 the first year in which the notification of poliomyelitis required separate returns of paralytic and non-paralytic cases, the proportion of non-paralytic cases was remarkably constant (20–40%) By contrast in 1951, between the 24th and 37th weeks there was a sudden rise to over 50% in the notifications of non-paralytic forms of poliomyelitis, the increase being greatest in the Midlands

The rôle of the Coxsackie group of viruses in the causation of this syndrome has been uncertain Several workers (Melnick et al 1949, Silverthorne et al 1951) have reported the isolation of Coxsackie viruses from patients diagnosed as having non paralytic poliomyelitis, but Smadel (1951), on the basis of serological studies, concluded that the Coxsackie viruses seemed to be of little importance in his group of patients

We describe here the cases seen by us in 1951 and the results of virus investigations

EPIDEMIOLOGY

In 1950 and 1951 (in contrast to 1947–49) the number of cases diagnosed in this hospital as non paralytic poliomyelitis showed a marked preponderance over those with paralysis (*table* I)

Non-paralytic poliomyelitis was diagnosed in the presence of fever, meningeal or meningo encephalitic symptoms, and an abnormal cell count in the cerebrospinal fluid (C S F), with or without an increase of protein, all occurring in the absence of paralysis or of not previously been used in an investigation of this kind. A suspension of particles can be introduced into the cranial subarachnoid space of the newborn rat with remarkable ease and little or no danger to its life. This has made possible for the first time the daily injection of an indicator into the cranial subarachnoid space of a laboratory animal over a long period, and consequently the introduction of a large amount of indicator relative to the size of the subarachnoid space.

MATERIALS AND METHODS

Newborn rats were anæsthetised with a mixture of chloroform and ether. After indian ink, colloidal silver, and colloidal silver iodide had been tried, 'Dag' colloidal carbon (Acheson Colloids) was found to be the most satisfactory indicator. On the day after birth each young rat was given an injection of 0·1 ml. of the indicator into the cranial subarachnoid space. After the injection the rat was returned to its mother. The injection was repeated daily, and the rats were killed at intervals up to three weeks.

The study of the pathways followed by the injected particles was facilitated by the dissection of the spinal cord and membranes under a binocular microscope, and by the preparation of whole cleared specimens and of sections of the rats stained by a variation of the Bielschowsky method and with hæmatoxylin and Van Gieson's stains.

OBSERVATIONS

In the region of the spinal canal the colloidal carbon collected in three main situations: (1) in the prevertebral lymph-glands, (2) in cuffs round the emerging nerve-roots, and (3) in the perivascular spaces of the spinal cord.

Prevertebral Lymph-glands

The lymph-glands on the posterior wall of the thorax and abdomen were clearly visible as black masses laden with colloidal carbon (fig. 1). This appearance was visible macroscopically within half an hour of the subarachnoid injection. In the thorax of rats allowed to survive for a while fine vessels, outlined by colloidal carbon, were seen running from the region of the nerve-roots to the lymph-glands.

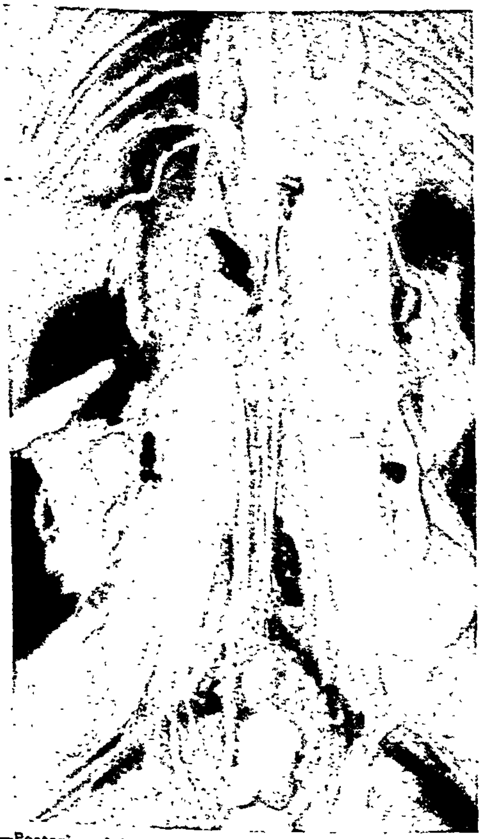

Fig. 1—Posterior abdominal wall of rat aged 21 days showing carbon particles in prevertebral lymph-glands.

Cuffs Round Nerve-roots

These were clearly outlined by large deposits of colloidal carbon (fig. 2). Both the cranial and spinal nerves presented these *Tuschenmanchetten* (Ivanow 1927). The subarachnoid cuffs were especially well filled round the nerve-roots contributing to the brachial and lumbosacral plexuses. Accumulations of carbon particles also outlined the vessels on the surface of the spinal cord.

Perivascular Spaces of Spinal Cord

These contained large amounts of carbon particles (fig. 3), especially in the perivascular spaces surrounding the vessels supplying the anterior horn.

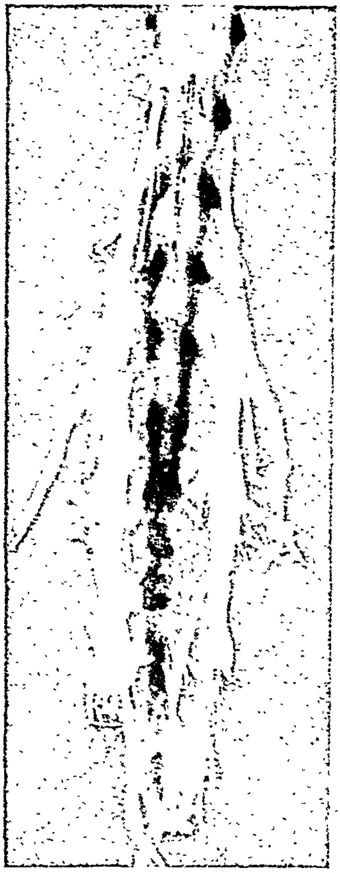

Fig. 2—Lower end of spinal cord of rat aged 21 days showing subarachnoid cul-de-sacs round anterior nerve-roots.

Summary

The path of particles introduced into the cranial subarachnoid space of the rat seems to be as follows. The particles pass rapidly down the subarachnoid space to the lower end of the spinal cord, being distributed freely through the C.S.F. They congregate in the subarachnoid cul-de-sacs surrounding the emerging nerve-roots and pass from these to the regional lymph-glands of the posterior abdominal wall. Later they tend to pass centripetally into the perivascular spaces of the spinal cord.

DISCUSSION

The experimental results briefly outlined above indicate that particles greater than the poliomyelitis virus can pass freely from the abdominal lymph-glands to the perivascular spaces of the spinal cord in intimate relation to the anterior-horn cells. Field and Brierley (1948b) have shown that the prevertebral glands are connected both with the lymphatics of the intestines and with the subarachnoid cul-de-sacs round the emerging nerve-roots. It therefore seems reasonable to infer that, in certain circumstances, ingested particles, especially if they are very small, might make their way from the intestines to the C.S.F. via the subarachnoid cul-de-sacs and thence to perivascular spaces of the spinal cord.

The nature and function of the perivascular spaces of the spinal cord are therefore matters of considerable importance. The flow of fluid in the perivascular spaces has been held by some workers to be from within outwards (Weed 1914, Schaltenbrand and Bailey 1927) and by others to be in the opposite direction (Mott 1910). The results obtained in the present investigation confirm

TABLE III—SUMMARY OF ABNORMAL C S F CELL COUNTS

Cells per c mm	No of cases	Polymorphs (P) predominant	Lymphocytes (L) predominant	P & L about equal
Up to 10	8	3	3	2
10–100	45	9	29	7
100–200	19	2	15	2
200–1000	16	5	10	1
1000–1500	2	1	1	0
Total	90	20	58	12

at the first lumbar puncture could be held responsible for these abnormalities That any significant quantity of air entered the theca during lumbar puncture appeared unlikely, and bloodstaining seldom accompanied the *taking of first specimens* Further, the mixture of normal and widely varying abnormal findings in the second specimens matched the findings in first specimens Therefore it was felt that the abnormalities on second testing were on the whole attributable to the illness

The 13 cases in which there were no abnormalities of the C S F, or were not present at the time of sampling, recall experience in poliomyelitis where normal C S F findings may occur even in the nervous phase (Paul 1951), indeed a wide range of C S F findings from normal to a lymphocytic or high polymorph pleocytosis—much as in this meningo-encephalitic series—has been reported (Martin and Elkington 1950)

The abnormal C S F cell-counts are summarised in table III

CASES IN WHICH VIRUS INVESTIGATIONS WERE MADE

CASE 1—Female, aged 15, admitted on seventh day of disease

C S F 10 polymorphs and 10 lymphocytes per c mm
Protein 40
Sugar 61 } mg per 100 ml
Chlorides 740

CASE 2—Male, aged 14, admitted on second day of disease

C S F 30 polymorphs, 34 lymphocytes and 160 red cells per c mm
Protein 60
Sugar 65 } mg per 100 ml
Chlorides 740

CASE 3—Female, aged 14, admitted on fifth day of disease

C S F *10 polymorphs and 30 lymphocytes per c mm*
Protein 40
Sugar 62 } mg per 100 ml
Chlorides 720

CASE 4—Male, aged 25, admitted on fourth day of disease

C S F (2 occasions) normal findings

CASE 5—*Female, aged 7,* admitted on fifth day of disease

C S F 250 polymorphs and 20 lymphocytes per c mm
Protein 40
Sugar 54 } mg per 100 ml
Chlorides 800

CASE 6—Male, aged 4, admitted on fourth day of disease; *a typical case of paralytic poliomyelitis*

CASE 7—Male, aged 12, admitted on third day of disease

C S F 60 polymorphs and 700 lymphocytes per c mm
Protein 40
Sugar 56 } *mg per 100 ml*
Chlorides 740

CASE 8—Male, aged 10, admitted with scarlet fever, four days after admission he had pyrexia 101°F, frontal headache, and neck rigidity

C S F 20 polymorphs and 70 lymphocytes per c mm
Protein 40
Sugar 50 } mg per 100 ml
Chlorides 720

This was possibly a mild case of postinfective encephalitis, not included in the totals of meningo encephalitis cases

VIRUS INVESTIGATIONS

Specimens of serum obtained in the acute and convalescent stages of the illness, and specimens of stools obtained on about the same day as the first samples of serum, were received from the 8 patients already described Details of the days, relative to the onset of illness, on which the sera were obtained are given in table IV The methods used in the preparation of stool suspensions for virus isolation and in making the neutralisation tests in suckling mice have been previously described (Kenyon et al 1952) The dilutions of serum refer to the initial dilutions before the addition of virus suspension

Isolation of Coxsackie Virus

A strain of one of the Coxsackie group of viruses was isolated from 1 (case 1) of the 8 stools investigated The stool had been obtained nine days after the onset of illness Histologically the newly isolated strain of virus caused lesions in the fat pads and brain of suckling mice and belonged to the B group of viruses By neutralisation tests it was found to be similar to the strain of virus isolated from the outbreak in a children's home in Coventry in 1951 (Kenyon et al 1952), but complete identification was not achieved

Isolation of Poliomyelitis Virus

As there was a possibility that the clinical condition resulted from infection by poliomyelitis virus, attempts at isolation were made by inoculation into rhesus *monkeys of individual or pooled stool suspensions* previously used in suckling mice Each monkey was given, under anæsthesia, 0 6 ml of suspension intracerebrally and 1 ml intranasally, the intranasal inoculation being repeated next day Daily temperature records were kept for three weeks after inoculation

TABLE IV—HUMAN SERUM NEUTRALISATION TESTS

Case no	Age (yr)	*Days* after onset of illness	Serum dilutions					Saline control
			1/1	1/10	1/50	1/250	1/1250

		21	3/11	0/6	6/6	—	—	8/8

(1) This indicates the number of mice which died as a result of *inoculation over the number of mice inoculated* Surviving mice were those alive when 3–4 weeks old
The figures given represent accumulated inoculations

No 1 monkey, which received a pool of equal volumes of stool suspensions *from cases 1 and 2, had a pyrexial* reaction on the sixth and seventh days after inoculation, without the development of paralysis Histological examination of the spinal cord removed twenty eight days after inoculation showed *no* evidence of poliomyelitis

No 2 monkey, which received stool suspensions from case 6, had a pyrexial reaction on the eighth and ninth days *after* inoculation, with paralysis on the tenth day, when the spinal cord was removed Histological examination confirmed the diagnosis of poliomyelitis

No 3 monkey, which *received a pool* of equal volumes of *stool suspensions* from cases 3, 5, and 7, showed no pyrexial reaction or evidence of infection Histological examination *of the spinal cord* removed twenty one days after inoculation showed no evidence of poliomyelitis

No 4 monkey, which received *stool* suspensions from case 6 showed no pyrexial reaction or evidence of infection No *histological* examination was *made*

The stool suspension from case 4 was not investigated in monkeys

The *stool suspension* from *case* 6 was inoculated intracerebrally into adult mice No paralysis was observed after two passages, each of *thirty days' duration* worthy of trial in the treatment of experimentally induced poliomyelitis.

SUMMARY

A new experimental technique has been used for studying the fate of particles injected into the subarachnoid space of newborn rats.

The implications which the results of these experiments have on the pathology and therapy of poliomyelitis are discussed.

We wish to thank Prof. J. D. Boyd for his advice and encouragement, Mr. R. Smith for technical assistance, and Mr. J. A. Fairfax Fozzard for the photographs. Messrs. Acheson Colloids supplied the colloidal carbon.

MEMBERS OF THE STATISTICAL RESEARCH UNIT OF THE MEDICAL RESEARCH COUNCIL

THE suggestion that administration of vitamin E is beneficial in peripheral arterial disease was originally made by Shute et al. (1948). Its use has been advised in the treatment both of angina pectoris and of intermittent claudication. In angina the earlier favourable claims (Vogelsang and Shute 1946, Vogelsang et al. 1947) were not confirmed by the more carefully controlled studies of later observers (Makinson et al. 1948, Donegan et al. 1949, Ravin and Katz 1949). On the other hand the administration of synthetic vitamin E in cases of intermittent claudication of moderate severity has been strongly advocated by Boyd et al. (1949), Ratcliffe (1949), and Boyd (1951), and as a result this drug is now widely prescribed.

If vitamin E acts by expediting the recanalisation of occluded arteries or the development of collateral arteries in cases of intermittent claudication, it is difficult to understand why it should not be equally effective in angina pectoris when this is due to occlusive coronary arterial disease. In a small series of cases of intermittent claudication Hamilton and Wilson (1952) found that synthetic vitamin E had no effect on exercise tolerance, which was measured at short intervals throughout the period of treatment.

In view of this conflict of evidence the action of vitamin E in intermittent claudication has been further investigated in a larger series of cases. On this occasion the natural product, as recommended by Shute et al. (1948), rather than the synthetic preparation, has been used.

TABLE I—SIMILARITY OF VITAMIN-E AND CONTROL GROUPS

(Table shows mean values with their standard errors for each group)

—	Vitamin E (20 cases). Mean ± S.E.	Control (21 cases). Mean ± S.E.
Age (years)	54·8 ± 1·8	55·9 ± 1·8
Duration of illness (years) ..	3·6 ± 0·5	3·3 ± 0·5
Exercise-tolerance tests:		
Average number of circuits ..	19·0 ± 1·6	18·1 ± 1·6
Average duration of pain after exercise (sec.)	42·0 ± 5·9	55·7 ± 5·8
Average time per circuit (sec.)	5·6 ± 0·2	6·5 ± 0·2

METHODS

41 patients have been studied. All had typical intermittent claudication of the calf muscles due to occlusive arterial disease. In only 1 patient was the arterial disease the result of thrombo-angiitis obliterans. In the remaining 40 cases the arterial lesion was assumed to be atheromatous. None of the patients had diabetes. Exercise-tolerance tests were made, so far as possible, at fortnightly intervals by walking over steps (Hamilton and Wilson 1952). The patient halted as soon as the pain in the legs developed. The number of circuits over the steps and the duration of the exercise were recorded, and the rate of walking was calculated. The duration of the pain after stopping was also measured. A full clinical examination was made before and after the course of treatment, and the patient's opinion about any change in his capacity to walk was ascertained.

Natural vitamin E was dispensed in gelatin-coated capsules, the specification for their preparation being that " the d. alpha tocopheryl acetate shall be prepared from vegetable oils and each capsule shall contain Type VI concentrate, equivalent to 75 mgm. d.l. tocopheryl acetate." Similar capsules were filled with arachis oil, and these control preparations were identical in size and colour with the vitamin-E capsules so that they could not be distinguished in any respect by either the investigators or the patients. During the twelve-week period of treatment two capsules were taken thrice daily. The dose of vitamin E was accordingly 450 I.U. per day.

Numbered sets of bottles containing either vitamin E or arachis oil were prepared in the Statistical Research Unit of the Medical Research Council; the order of administration of the two treatments was based upon a list randomly constructed in the unit and held there. After a preliminary period of observation of at least a month, the patient was allotted a number and took the similarly numbered capsules continuously for twelve weeks. The investigations were continued for a further month after the period of treatment. The nature of the treatment in individual cases was not revealed to the investigators until after the whole trial was completed.

COMPARABILITY OF GROUPS BEFORE TREATMENT

As the treatment allocated to each patient was determined randomly, a careful comparison of those receiving vitamin E and those receiving arachis oil is essential. This has been based on the observations made before treatment, and the results are shown in table I. The mean age and the mean duration of the illness are similar in both groups. For each patient the number of circuits walked before the onset of pain was recorded at each visit before treatment, and from these observations the

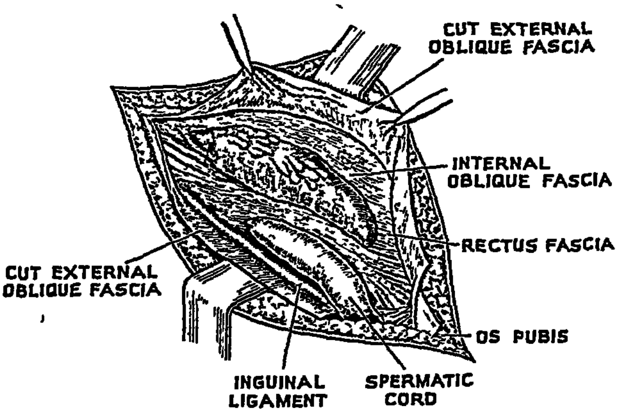
AN UNUSUAL TYPE OF HERNIA

STANFORD HOWARD
B M Oxfd, F R C S
SURGEON TO THE BURNLEY GROUP OF HOSPITALS, LANCS

THE hernia described below was, to me at least, unique, for in a long experience of operative surgery I have seen nothing similar Clinically it so much resembled the common type of indirect inguinal hernia that the routine procedure was adopted, and the exact relationships of the sac were not recognised until the area had been fully dissected

A man, aged 42, gave a six months' history of a swelling in his right groin This was said to be getting slightly larger and causing aching or dragging pain He had had no previous operations

On examination he was well built and muscular In his right inguinal canal was a well defined fusiform swelling which transmitted an expansile impulse on coughing and extended as far as the external ring It was easily reducible



The hernia fully exposed at operation

An indirect inguinal hernia was diagnosed and the patient was in due course admitted to hospital for operation

Operation —When the inguinal canal was opened through a routine incision over it, the spermatic cord was seen to be normal No sac was connected with the cord The external ring was normal, the cremaster muscle was well developed, and the testis was normal There was no sign of a direct hernia This was puzzling in view of the clinical signs, which had been so clear at the first examination and had been confirmed by the surgical registrar when the patient was admitted The external oblique muscle was therefore incised a little further, and retraction of the upper flap of the aponeurosis exposed a long thin process of fat lying above the cord, parallel with it and about $^1/_2$ in from it (see figure) To trace this pad of fat back to its origin, the incision in the external oblique was extended another inch laterally, whereupon it was evident the process was issuing through a gap in the internal oblique muscle at a point about $1^1/_4$ in lateral to and $^3/_4$ in above, the internal ring The fatty process was then dissected and was found to contain a well established peritoneal sac about 3 in long and $^1/_2$ in in diameter at its widest point The opening in the internal oblique muscle was oval, about $^1/_2 \times ^1/_4$ in , with fibrosed and thickened edges The sac contained omentum Repair was effected by removal of the sac, freshening the edges of the gap in the internal oblique muscle, and suturing with floss silk Further reinforcement was obtained by overlapping the aponeurosis of the external oblique muscle The result of the repair has so far (twenty months after operation) been good

It is a little difficult to determine why such a hernia should appear, unless it were due to a congenital defect in the internal oblique muscle , but, if this were so it is also difficult to understand why no hernia should have developed until after more than forty years of life There was no history of sudden strain or violence which might have torn fibres of the internal oblique muscle The only other suggestion I offer is that it was a traction hernia caused by a pad of properitoneal fat which insinuated itself between the muscle-fibres and pulled a process of peritoneum after it

This hernia must really be classed as an interstitial hernia (Noonan 1950), but it is surely unusual for an interstitial hernia to present in the inguinal canal in such a way as to simulate an indirect inguinal hernia The diagnosis of interstitial hernia is always difficult, particularly when it is immediately properitoneal—i e , deep to the transversalis muscle—and, in fact, strangulation takes place in many cases before the diagnosis is evident

It would be interesting to know whether any similar case has been observed

New Inventions

A PROTECTIVE HOOD FOR LABORATORY BURNERS

THIS device is designed to prevent the scattering of infective material from wire loops when these are flamed It consists of three detachable parts, and can be made in a moderately well-equipped workshop

It was found, during experiments with different designs, that the main problem was to allow adequate ventilation without permitting the escape of infective material If insufficient air were admitted, the enclosed bunsen flame would lose its normal size and shape, and, unless the alternative exit were large enough, hot air would escape through the slit cut for insertion of the loop, burning the operator's hand Both these difficulties were overcome by baffled ventilation holes in the top and base as illustrated

The base, which is supported by a tripod, consists of a rimmed metal disc with a ring of small holes at the periphery To prevent any escape through them of infective material, they are guarded above by a flat baffle ring A central hole admits the burner and fits

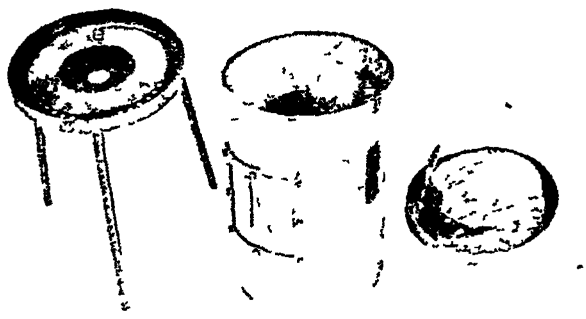

Fig 1

in their duration of pain—i.e., comparing the pre-treatment and treatment periods. Thus, for each extra second in the original time that a patient took per circuit there was, on the average, a 6·7% increase in the duration of pain observed during treatment (the regression coefficient of 6·7 has a S.E. of 3·2 and is therefore significant at the 0·05 level). It has already been shown (table I) that the vitamin-E group has a mean time per circuit of 5·6 seconds, compared with 6·5 seconds for the controls. This difference, which to two decimal places is 0·85 seconds, would alone be expected to cause a subsequent difference between the two groups in the percentage change in duration of pain—i.e., (0·85) (6·7) = 5·7%. The observed difference of 18·0% in table VII should therefore be reduced by 5·7 to give the correct value, 12·3%. This corrected value still favours the vitamin-E group, but it has a standard error of 7·2% and is thus not technically significant, although it is sufficiently nearly so to require further consideration.

These observed changes in the duration of pain during the course of treatment were also analysed in relation to the treatment schedule. Table VII shows that the relative improvement of the vitamin-E group, compared with the deterioration of the control group, was slightly more distinct in the first two months' treatment than later. The corrected difference of 15·5% just reaches significance at the 0·05 level. In the third month of treatment and in the post-treatment period the differences, on the other hand, are not significant. In both groups in the post-treatment period the changes from the pre-treatment level are quite small and unimpressive.

The rather small numbers of patients available in this trial may have led to moderate effects of vitamin-E treatment not being detected, owing to the considerable variability between patients. It is therefore of some interest to record the probable upper and lower limits to the effects of vitamin-E treatment as revealed by these controlled observations. These points are "95% confidence limits," between which the true mean effect is likely to lie. They are obtained by taking the observed differences in means given in tables IV–VII, and adding to, or subtracting from, them "t" times the standard error. (The factor t is the 0·05 level of the t-distribution on N-2 degrees of freedom, where N is the total number of patients used in the comparison. For a comparison using all the patients, as in table IV, N = 41 and t = 2·02.) The odds are 19 to 1 that the two limits include the true mean value for the type of patient used in this trial. The limits are given in table VIII. Those for increases in exercise tolerance probably exaggerate the possible beneficial effect of vitamin E, owing to the original disparity of the groups. In the calculation of limits for the percentage change in duration of pain the corrected value of table VII has been used.

TABLE VII—CHANGE IN AVERAGE DURATION OF PAIN DURING AND AFTER TREATMENT AS PERCENTAGE OF PRE-TREATMENT AVERAGE

Period	No. of cases	Mean ± standard error	After correction for time/circuit	Regression of percentage increase in pain on time/circuit
0–12 weeks' treatment	20	Vit. E −9·7 ±5·0		
	21	Control +8·3 ±4·9		
		Difference −18·0 ±7·0	−12·3 ±7·2	6·7 ±3·1
0–8 weeks' treatment	20	Vit. E −10·2 ±5·4		
	21	Control +11·7 ±5·3		
		Difference −21·9 ±7·5	−15·5 ±7·7	7·5 ±3·3
8–12 weeks' treatment	20	Vit. E. −10·0 ±5·0		
	19	Control +4·9 ±5·1		
		Difference −14·9 ±7·1	−11·4 ±7·6	4·4 ±3·5
Post-treatment period	19	Vit. E −8·5 ±6·5		
	20	Control +5·2 ±6·3		
		Difference −13·7 ±9·1	−12·0 ±9·9	1·9 ±4·3

TABLE VIII—95% CONFIDENCE LIMITS FOR MEAN EFFECTS OF VITAMIN E IN COMPARISON WITH CONTROLS

Comparison	Limits
Table IV—Average increase in circuits during treatment	− 1·7 to + 3·1 circuits
Table V—Average increase in circuits during last month of treatment ..	− 2·2 to + 3·4 circuits
Table VI—Average increase in circuits after treatment	− 3·4 to + 2·3 circuits
Table VII—Average change in duration of pain, as percentage of pre-treatment level	− 26·8% to + 2·3%

DISCUSSION

In determining the results of treatment reliance has been placed on the statements of the patients, the clinical examination of the lower limbs, and the performance of exercise-tolerance tests. Neither of the first two indicated that vitamin E was in any way superior to arachis oil. In the exercise-tolerance tests treatment produced no marked or technically significant difference between the two groups as regards the distance that could be walked before the onset of pain. The only difference of any substance found between the two groups was in the duration of pain after exercise. During the whole period of treatment this increased by + 8·3%, on the average, in the controls and decreased by − 9·7% in the vitamin-E group. The difference between the two figures was shown to be significant. The statistical analysis of the results also showed that the duration of pain after exercise tended to become significantly greater in the slow walkers in both treatment groups as the trial proceeded. These slow walkers were initially rather more numerous in the control group; and, if a correction is made for this discrepancy, the difference between the two groups is no longer technically significant, though it continues to favour slightly the patients on vitamin E.

From the clinical point of view, however, too much importance should not be attached to these results, because the assessment of the duration of a pain that gradually fades away is notoriously difficult, and there was considerable variability in these measurements even in the same patient. It will be noted that the changes from the pre-treatment values are small in each of the two groups, and they are of significance only because they are in opposite directions. A more detailed analysis of the results showed that the difference between the two groups was greatest during the first two months' treatment but was non-significant during the third month and the period immediately after treatment. This is the reverse of what might be expected if the changes were the result of vitamin-E therapy.

The results of this investigation have shown that the beneficial effect of vitamin E in the treatment of these cases of intermittent claudication was not appreciably greater than that of arachis oil, and the earlier favourable reports of Boyd et al. (1949) have not been confirmed. Our failure to demonstrate improvement could be due (1) to the methods of assessement being insufficiently exact, with the result that a real improvement was overlooked, or (2) to the wrong type of patient being treated. In our exercise-tolerance tests the patients walked over steps, whereas in Boyd's series they walked on the level, either along hospital corridors or on a moving platform. The two methods, however, are fundamentally similar because they both measure the amount of exercise required to produce pain. A true improvement is reflected in an increase in the amount of exercise that can be taken before the onset of pain and in a decrease

Alcohol, Culture, and Society

CLARENCE H PATRICK, professor of sociology, Wake Forest College, North Carolina Durham, N C Duke University Press London Cambridge University Press 1952 Pp 176 22*s* 6*d*

THE sociologist is concerned with human culture in so far as it provides the means by which man, even in the most primitive societies, creates around himself a secondary world where he can look for the satisfaction of his biological needs even the Bushman is not wholly dependent on his natural environment, as the animals are From prehistoric times, alcohol has supplied a human cultural need, and it is with the use of alcohol, the underlying purposes of this, and the effects on both the individual and society, that Professor Patrick is dealing in this compact study

From time immemorial alcohol has been a problem potent for good and ill Greek and early Roman moralists disapproved of its use, but the Indo Aryan tribes of India about 1000 B C believed that their god, Indra, was only capable of heroic deeds when intoxicated England in the 17th and 18th centuries was notoriously intemperate, landlords of gin houses used to hang signs out offering the customer enough gin to get dead drunk for twopence, and free straw to lie on The Pilgrim Fathers were by no means teetotal, and from the 18th century onwards a taste for distilled liquors (obtainable from the West Indies as rum) rather than for wines and beer (obtainable only from the Old World) was making itself felt Present day drinking habits in the United States vary according to social class, in the working class and the upper class men and women drink together, whereas in the middle classes this is frowned upon

The great influence of social *mores* on drinking patterns is discussed, and also the attempts being made by the U S liquor trade to influence these by skilful advertising campaigns

Störungen der Fettresorption im frühen Säuglingsalter

FRITZ HAUSER, Privat Dozent in the University of Basle Basle and New York S Karger 1953 Pp 108 Sw fr 14

THIS treatise from the pædiatric clinic of Basle University is obviously strongly influenced by the teachings of Verzár After a discussion of the theories of fat absorption the author comes down heavily on the side of complete hydrolysis of triglycerides with subsequent resynthesis in the intestinal mucosal cell Frazer's opposing theory of partial hydrolysis and of predominantly particulate absorption of unsplit fat is summarily rejected It is a pity that Dr Hauser gives us no references to what he describes as Verzár's recent unanswerable counterarguments, and that he has followed Frazer's publications only up to 1946 an acquaintance with the more recent work would have prevented him from misinterpreting Frazer's ideas on the fate of long-chain fatty acids The main part of the text deals with disturbances of fat absorption due to disease, but in many of the 21 cases described fat absorption was not studied at all, and their inclusion is puzzling The last chapter contains some interesting points on the management of disturbed fat absorption in premature infants

Wounds of the Extremities in Military Surgery

OSCAR P HAMPTON, JUN, M D, F A C S, instructor in clinical orthopedic surgery, Washington University London Henry Kimpton 1951 Pp 434 70*s*

DR Hampton's distinguished service with the American Army in the Mediterranean theatre of war forms the basis of his beautifully produced book His first four chapters deal with such things as first-aid, the initial surgery of wounds in forward areas, and reparative surgery at base hospitals He then discusses special injuries of bones, vessels, nerves, and joints, as well as amputations, burns, and regional injuries There is a certain amount of overlapping, but the arrangement makes for easy reference

With the main themes of Dr Hampton's teaching his colleagues in the British Army would agree, but there are some points on which they may differ Having admitted the advantages of the open flap method for amputations in the forward area, and made a strong case for it, he advocates guillotine amputations He advises the hip spica for the transport of fractured femurs—though of all the awkward, bedsore making pieces of apparatus for loading into and out of ambulances, the hip spica takes first prize Fortunately he gives a full page of diagrams showing the application of the Tobruk splint, which, though it may not hold the fragments quite still, permits of traction and of comparative comfort during transport, and does not necessitate the patient being turned sideways to get him through a door The three pages on burns seem unduly brief for injuries which often present an exceedingly difficult problem

Wounds of the limbs exceed in number all other wounds, and this lavishly illustrated book would be a good companion for any surgeon who had to return to war surgery Moreover, the principles of traumatic surgery do not vary whether wounds are inflicted by design or accident, and many an industrial or road accident would be better handled if all surgeons had read this book

The Measurement of Hearing

IRA J HIRSH, Central Institute for the Deaf and Washington University, St Louis, Missouri New York and London McGraw Hill 1952 Pp 364 51*s*

THIS book is one of a large series of publications on psychological problems, and has been written for such diverse professional persons as the experimental psychologist, the clinical otologist, acoustic and communication engineers, and the physicist interested in sound The lucid explanations of the principles of sound production and electro-acoustic equipment are helpful for the understanding of the various clinical procedures adopted in most clinics and laboratories today Similes are used well to simplify technical points, and the meaning of such terms as difference limen, discrimination loss, recruitment, and social adequacy index is made clear The psychological aspects are so practical and physiologically rational that they will appeal to both otologists and laymen Mention might have been made, however, of such subjects as tone deafness, the appreciation of music, and the relative intelligibility of different languages to people with different degrees of deafness The book should certainly be read by all those interested in acoustics Many otologists would benefit from the clear and logical explanation of the science of audiology

Rheumatic Diseases

Diagnosis and Treatment EUGENE F TRAUT, M D, F A C P, associate (Rush) clinical professor of medicine University of Illinois London Henry Kimpton 1952 Pp 942 150*s*

DR Traut says that in the United States 7½ million persons have "rheumatism," and 30 million have a deep personal concern in joint disease of these, 1½ million have degenerative joint disease He has accordingly attempted to assemble material on this subject which is accepted as factual by current authorities He has tried "not to display unjustified enthusiasm and devote too much space to discussions of the exciting new endocrinologic therapy of rheumatic diseases", and the rather disappointing result is that only half a dozen pages in this very large book are devoted to the actual treatment of rheumatoid arthritis with cortisone and A C T H He advocates the use of a stock vaccine made from a greening streptococcus of low virulence, which he regards as an indispensable part of his armamentarium Of gold therapy he says "it is questionable whether chrysotherapy for arthritis deserves extensive consideration"—an opinion that would not be generally accepted on this side of the Atlantic The chapter on physical medicine follows current practice, and includes a number of simple and valuable exercises for the daily use of the patient, and the interesting chapter on the ocular manifestations of rheumatic disease is a welcome innovation In the chapter on fibrositis Dr Traut pays tribute to the pioneer contributions of the British, though the only British reference given is to a book published in 1919 Indeed, there are very few references to papers of non-American origin, which is a considerable weakness This well-produced but expensive volume gives an interesting review of the beliefs of the author and his colleagues in Chicago, but does not present so wide or impartial a view of rheumatic diseases as do "Comroe" and other well-established American books on rheumatology

RESULTS

In all cases the carbon dioxide content of expired air rose abruptly from zero after clearance of the anatomical dead space. In what follows "expired air" will refer to that part of the breath after this abrupt rise has taken place.

Our results confirm those of the previous workers. In six normal persons the carbon dioxide content climbed

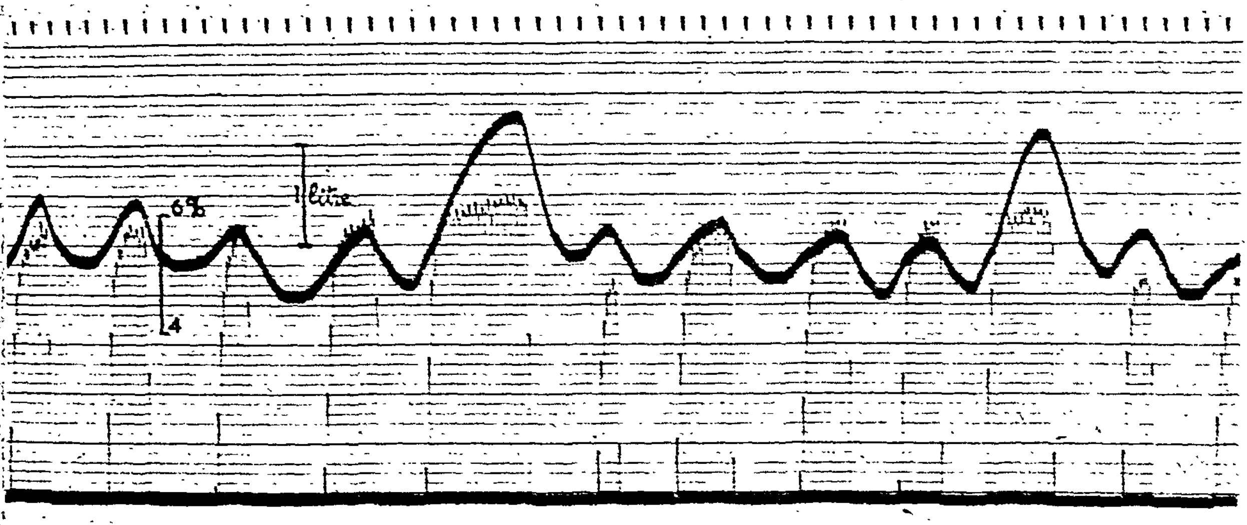

Fig. 2—Normal spirometric and carbon dioxide record: a large expiration does not entail an increase in carbon dioxide content of expired air.

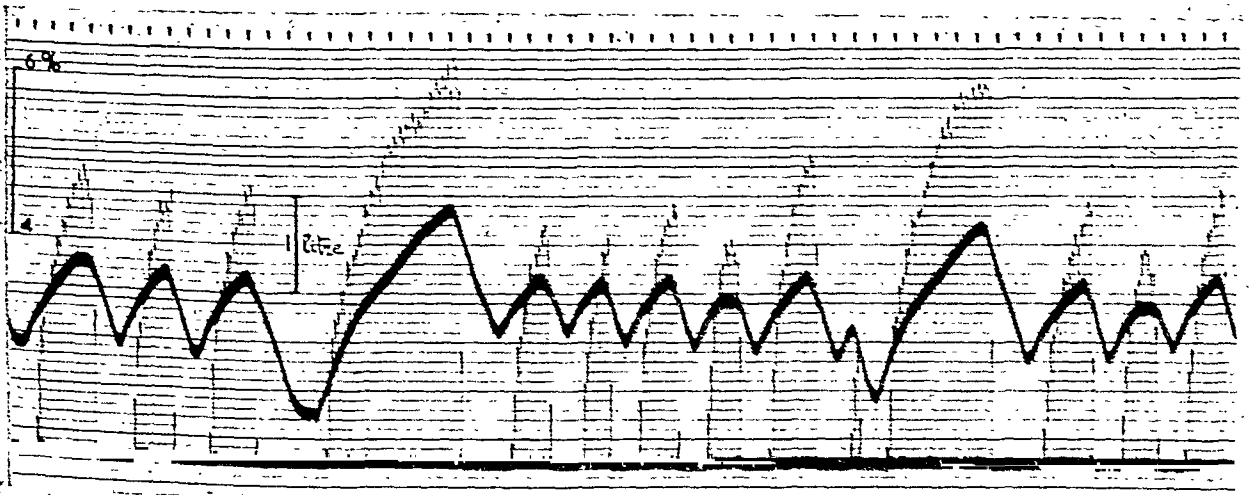

Fig. 3—Spirometric and carbon dioxide record in emphysema: carbon dioxide level varies with volume of expired air.

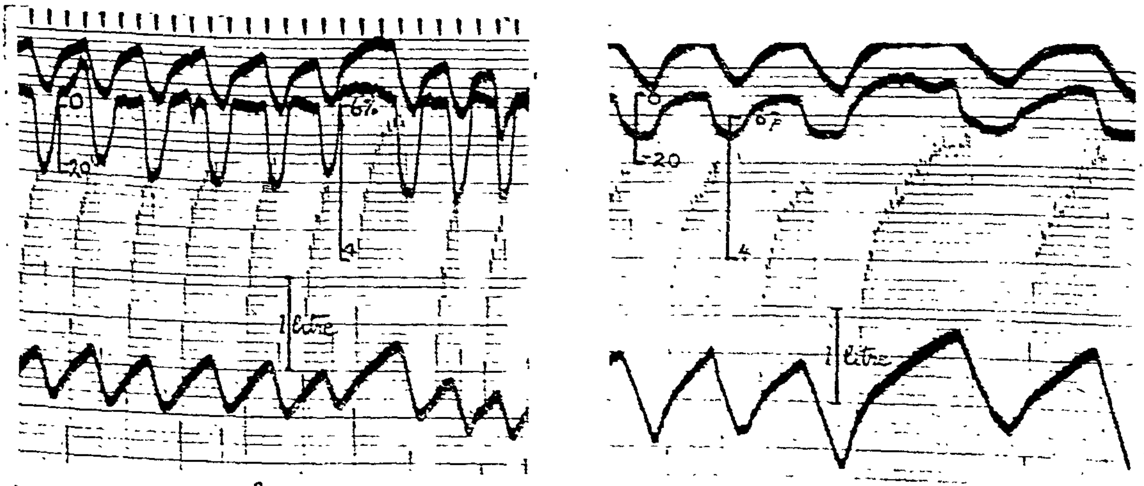

a b

Fig. 4—Records (from above down) trunk movement, intrathoracic pressure (mm. Hg), carbon dioxide content, and spirometer: *a*, during severe asthma (note large intrathoracic pressure swing); *b*, after spontaneous improvement. (Carbon dioxide record is still abnormal.)

of all the periods spent by the trained staff in teaching, and was distributed, over the week, among all the students working in the ward—who might number anything from 8 to 2. Some sisters said that they made the giving and receiving of reports an occasion for explaining new cases to student nurses, but several said they did not explain new cases to students: they thought the information would probably “ filter through.”

The students receiving this diminutive instruction were doing 74% of all the nursing done in the wards. Nor were they engaged entirely on what the team agreed to call “ basic ” nursing procedures, meaning “ those nursing duties having their origin in the physical needs of the patient ” (they define these further in a list). Students also took some share in “ technical ” nursing, classed here as the care given as a result of the disease from which the patient is suffering; this includes such things as helping the medical staff with technical procedures, giving medicines, taking pulses and temperatures, doing dressings, giving injections, preparing patients for operations, checking drugs, stockmaking, testing urines, and looking after patients returned from operation. In one ward student nurses were responsible for taking blood-pressures. It is noteworthy that 72% of the total time spent on dressings was contributed by students. Students also have to take responsibility when the sister and staff nurse are both out of the ward together—as may happen when one of these seniors is on holiday. On night duty a student nurse is regularly left alone in charge of a ward while her companion is taking a meal. There can be little opportunity, the report says, for trained staff to supervise the work done by student nurses (for instance, in the dressing of wounds) and virtually none for giving practical instruction. No doubt the student is taught the theory of wound dressing by the sister tutor, but on the job she has to pick up her practical technique from her seniors in training. This recalls the monitoring system of the old national schools, where a child who had got his letters taught them to a group of smaller ones. It is a useful makeshift when teachers are scarce, but it cannot be classed as efficient training.

The student nurse is so little of a student and so much of a nurse for the same reason that the ward-sister is so little of a nurse and so much of a clerk. Besides having to attend any doctor at any time, and for whatever purpose, he may choose to visit the ward, the ward-sister also has to do a great amount of form-filling, report-writing, telephoning, and stock counting—all important duties from the administrative standpoint, but emphatically not nursing. In short, as the report says, the end-result of nurse training in the hospital service is not nursing but administration. Only 16% of the time spent on nursing in these wards was contributed by State-registered nurses, and for a considerable part of the day, when the staff nurse was off duty, the sister was usually the only fully trained nurse on the ward, and vice versa.

Matters would be easier to arrange, no doubt, but for the inflexible obstacle of the patient and his needs. He must be wakened, washed, eased, and fed—all, by ancient custom, before the medical staff appear on the ward. The peak period of work in the morning thus occasions an unnaturally early start to the patient's day. This, the team found, begins on an average at 5 A.M. and ends at 10 P.M., and there is little chance for him to sleep undisturbed in between. The amount of work expected of the night nurse, in preparation for the morning peak, is beyond her capacity if the patient is to be wakened at a reasonable hour. The physical needs of patients, the report points out, cannot be altered; so any attempt to eliminate peak periods of work for nurses must depend on the cooperation of the medical staff and other specialist services. The team do not offer any evidence that this has been forthcoming so far, though they politely abstain from criticism.

Their suggestions for a better way of doing things turn on the proposal that nursing should be done by trained nurses, and not merely supervised by them. Basic nursing, they say—and we warmly agree with them—should not be delegated to an auxiliary grade, nor should nursing be thought of predominantly as a matter of exercising special technical skills. Each trained nurse, they suggest, should be responsible for a specified group of patients, “ a nursing unit,” and should have the help of nursing auxiliaries who may be either student nurses, assistant nurses, pupil assistant nurses, or orderlies. Trained nursing skill would thus be conserved for its “ proper ” task, the whole nursing care of the patient. This could be done, they believe, by reallocating many non-bedside tasks, by providing adequate nursing equipment and labour-saving devices, by revising working hours of staff to provide enough hands at peak periods and by having more reliefs. It will be possible only if the status of trained staff in hospitals is made attractive enough to persuade nurses to remain at work there. The ward-sister should, as now, be chief administrator, with complete responsibility for the care of her patients; but she should have as her right-hand woman a personal secretary, like other busy and responsible people. She would thus have time to teach her students, and they would have time to pause and learn. This is one of the experiments which has long deserved a trial, and there are others—such as a shortened course for students—with which it might well be combined. Such experiments have been advocated, on general principles, for a long time. But this report gives the backing of fact which those advocating such experiments have long needed. It does not bring to light much that critics of nursing training have not known or guessed; but their generalisations can no longer be set aside as mere opinion. Here are facts.

Acute Respiratory Insufficiency

Of the many patients now suffering from a seasonal exacerbation of respiratory disease a fair number present a clinical picture familiar yet little discussed and without an agreed name. Around London this winter their number was much increased by the severe fogs. Such a patient is commonly a man in late middle age who has had a cough for some years and has become moderately short-winded. Quite suddenly his condition becomes very much worse, with urgent dyspnœa and severe general upset. His face has a purplish flush; his eyes are bloodshot; his lips and tongue are cyanosed; his hands are warm; and his pulse is rapid and full. The jugular venous pressure may be raised, and if the condition has persisted for

TABLE I—ADMISSIONS OF PARALYTIC AND NON-PARALYTIC CASES 1947–1951

Year	Paralytic cases	Non-paralytic cases	Percentage non-paralytic
1947	21	16	43·2
1948	5	5	50·0
1949	22	14	38·8
1950	27	79	74·5
1951	14	90	86·5

evidence indicating a different ætiology. 90 such cases were admitted in 1951, and 22 clinically similar cases (table II) had normal C.S.F. cell-counts, although 9 of these gave a C.S.F. protein content of 60–80 mg. per 100 ml. In all, 112 patients were admitted to hospital with a similar clinical picture and were drawn from a predominantly urban population living either in, or within ten miles of, Coventry, a city of over 250,000 inhabitants, which itself accounted for 100 of the cases.

The admission-rate rose in May, continued at a high level until the end of July, and then dropped sharply. The fall roughly corresponded with the advent of the local holiday week and of school holidays.

During the peak months 1 case each of tuberculous, pneumococcal, and *Hæmophilus influenzæ* meningitis were seen; on admission they were indistinguishable clinically from the more severe of the meningo-encephalitic cases.

Multiple cases in families were probably not uncommon—e.g., a girl, aged 11 years, admitted in June, had meningeal signs and a C.S.F. cell-count of 140 per c.mm., while about the same time all the four other children in the family, aged 3, 5, 7, and 12 years, were ill but nursed at home.

Children of school age accounted for 55% of cases; the youngest patient was aged 6 months and the oldest 49 years.

Judged by history and pyrexia the duration of illness was 3 days or less in 20%, 4–7 days in 54%, 8–10 days in 18%, and 11–14 days in 8% of cases.

GENERAL CLINICAL DESCRIPTION

The onset of illness was sudden, with pyrexia commonly between 101° and 103°F. In cases lasting three days or less, severe headache and signs of meningeal irritation developed immediately. In cases of longer duration it sometimes seemed possible from the history to distinguish a premeningeal phase with pyrexia and moderate headache, generally lasting one or two days; in such cases a remission of from a half-day to two or three days occurred between the phases.

A mild sore throat was an early symptom in 27 (22)[*] patients; faucial congestion was noted in about the same number but without exudate. Herpes labialis occurred in 5 (4) patients aged from 11 years to 40.

Vomiting (often repeated) occurred in 73 (60) patients but seldom persisted after admission to hospital; 6 (5) others had nausea only.

Backache occurred in 19 (12) patients, and general limb aches in 10 (7) patients. Other sharp ill-localised and intermittent pains, sometimes persisting for a day or two, were recorded as follows: chest and shoulder girdle 6 (5) patients, abdomen and pelvic girdle 13 (9) patients, limb or limbs 5 (4) patients, head and face 3 (2) patients. In all, only 41 (30) of the 112 (90) patients complained of one or other form of these "muscular" aches and pains.

Headache, frontal and occipital or both, was constant and often said by older patients to be the worst they had ever had. Spinal rigidity was also constant, in degrees varying from slight to severe, though never so severe as to cause head retraction or opisthotonos. Neck rigidity sometimes occurred without dorsolumbar rigidity, and less often the converse obtained. Kernig's sign was recorded 50 (38) times, and photophobia 6 (4) times. In 6 (5) cases the knee-jerks or the ankle-jerks were temporarily unobtainable; plantar responses were always flexor. 1 (1) female adult had retention of urine. There were no paræsthesiæ other than history of pins-and-needles at onset in 1 case.

In 26 patients there were, in addition to headache, other cerebral features (sometimes in combination)—irritability or delirium 12 (10) cases, drowsiness or stupor 7 (6) cases, convulsions 6 (6) cases (ages varying from 7 months to 11 years), and diplopia 3 (3) cases. These features and the meagre C.S.F. changes in some cases seemed to justify use of the term meningo-encephalitis for the whole series. The C.S.F. findings in these 26 cases matched those in the more purely meningeal cases. Encephalitic states could be very brief, as in a man who had returned to work during a remission and, feeling nauseated, visited the lavatory only to fall promptly into a stupor, from which he "woke up" about an hour later. Other signs of possible encephalitic origin were flushing and profuse perspiration in 3 (3) cases, and giddiness in 2 (1) cases; vomiting in some cases occurred with the nervous phase. In 21 (14) cases brief nystagmoid movements of doubtful significance were elicited (4 of these patients had mental changes). The 3 cases already mentioned as having diplopia had no other paretic manifestations, and it was felt unlikely that they were poliomyelitis. No strabismus was observed.

Treatment in all the cases was symptomatic only, and recovery was invariably rapid and without, so far as is known, any sequelæ.

C.S.F. FINDINGS

The C.S.F. was usually clear and under moderately increased pressure judged by rate of drip. In at least 1 case it was opalescent (cells 702 per c.mm., mainly lymphocytes). Cell-counts and examination of cell types and of the protein, chloride, and sugar contents were routine; culture was not usually done except where it was felt that tuberculosis had not been excluded, or where the C.S.F. was opalescent or turbid. In all the cases rapid recovery ensued without chemotherapy.

TABLE II—ADMISSIONS OF PARALYTIC AND NON-PARALYTIC CASES 1951

Months in 1951	Paralytic cases	Originally classified non-paralytic cases	Additional non-paralytic cases (normal C.S.F. cell-count)
Jan.–April ..	2	7	1
May–Aug. ..	9	77	18
Sept.–Dec. ..	3	6	3
Total ..	14	90	22

Abnormalities were found in cell-counts (limit of normal taken as 5 lymphocytes per c.mm.) and in protein contents (normal range taken as 20–40 mg. per 100 ml.), but the chloride and sugar values varied within normal limits. Abnormal cell-counts occurred in 90 cases and in all save 3 the cells were a mixture of polymorphs and lymphocytes; the 3 exceptions had counts of only 4 or 5 per c.mm., all the cells being polymorphs. The amount of protein was increased mostly to 50–100 mg. per 100 ml. in 39 cases, in 30 cases accompanying a pleocytosis, and in 9 others a normal cell-count. In 13 cases no abnormality was found, but 2 of these each had a sibling concurrently ill and having a C.S.F. pleocytosis.

In 26 out of 31 cases in which the first sample of C.S.F. gave normal cell and protein findings a second diagnostic lumbar puncture was done at an interval of from two days to about a week. 14 of the second specimens gave abnormal cell-counts ranging from 5 polymorphs per c.mm. to 335 cells per c.mm. (mainly lymphocytes); 4 others had a slight increase of protein (60–80 mg. per 100 ml.); and 8 still gave normal findings. It was queried whether trauma, hæmorrhage, or entry of air sensitivity unimportant The W H O investigators have wisely begun by concentrating on a close study of these skin reactions, and they have used them to determine, among other things, the effect on the vaccine of storage, heat and light, and variations in preparation and concentration, as well as the results of mixing living and dead bacilli and varying the technique of intracutaneous vaccination The results were summarised by PALMER [6] and discussed in these columns [7]

---

[*] The figures in parentheses are cases with abnormal C.S.F. cell-counts.

Perhaps one of the most important contributions of the W.H O team is their insistence that tuberculin sensitivity is quantitative and not a simple qualitative phenomenon that may be described as present or absent, positive or negative They produce convincing evidence that the sensitivity of groups of people cannot be adequately described by such inexact and often almost meaningless estimates as the "percentage of positive reactors" The skin reactions must be measured and the level of tuberculin sensitivity expressed in terms of the distribution and mean size of the reactions in the group as a whole In this way it is possible to discriminate differences between groups that might be missed by less precise methods The accurate measurement of the diameter of the indurated area requires skill and practice Even with experienced workers the experimental error is not insignificant,[8] and with those less experienced it may be very large But if the tuberculin skin reaction continues to be looked upon (and described to students) as a rough qualitative test, no-one will trouble to acquire skill in its use Many investigations have shown how valuable the quantitative use of the reaction can be For example, BENTZON [9] demonstrated changes in tuberculin sensitivity during some of the infectious diseases, and MEYER [10] studied the standardisation of tuberculin preparations in man Careful measurement of the reactions during the preliminary skin-testing in the W H O investigation revealed some interesting differences in the patterns of tuberculin sensitivity in the countries concerned [11] These differences could not have been found if the all-or-none method of recording results had been used The frequency-distribution of the reactions to small doses of P P D tuberculin showed that there seemed to be three main kinds of tuberculin sensitivity—high-grade and low-grade sensitivity and relative insensitivity The high-grade sensitivity is thought to be due to infection with *Mycobacterium tuberculosis*, but certain characteristics of the low-grade sensitivity, coupled with earlier and similar observations in the U S A,[12] suggest that this sensitivity is independent of true tuberculous infection Low-grade sensitivity, it seems, has much to do with geographical factors, for example, it was much commoner in India and Egypt than in Denmark and Mexico City, and in the mountainous area around Darjeeling low-grade sensitivity was commoner in the low-lying valleys than in the higher tea plantations [13] This sensitivity, it is suggested, may be due to infection with an organism antigenically related to *Myco tuberculosis* Perhaps this explanation is an over simplification, but the hypothesis, if true, has many important implications For instance, the results of tuberculin surveys expressed in "percentage positive" figures may not be valid measures of the frequency of tuberculosis in a population It may well be that surveys in some countries have overestimated the prevalence of the disease The W H O monograph is concerned only with tuberculin sensitivity, and the authors have avoided accepting the assumption that a large local reaction and a high level of skin-sensitivity indicate immunity and a "successful" vaccination Their work shows that the local reaction and the sensitivity are much influenced, sometimes independently,[14] by many factors in the preparation and administration of the vaccine If local reaction, sensitivity, and immunity run parallel with one another, the immunity produced by the many million vaccinations so far performed must be extremely diverse in both degree and value But there is little evidence at present to justify the belief that the vaccination lesion or the postvaccination sensitivity are necessarily reliable measures of the production of immunity

The past year has brought two new reports of extensive investigations into the results of B C G vaccination DAHLSTROM and DIFS [15] studied the tuberculosis morbidity in over 60,000 conscripts to the Swedish army they found that the incidence of primary tuberculosis in those not vaccinated was approximately five times as high as in those vaccinated, and the incidence of postprimary tuberculosis was about three times as high ARONSON and ARONSON [16] have continued their work among groups of Indians in the U S A and Alaska Their assessment of B C G is based on carefully compiled mortality figures During 15 years' observation the mortality from tuberculosis was six times as high in the non-vaccinated as in the vaccinated Although the method of allocating the children to the groups was unfortunately not up to the highest statistical standards, this report, added to the latest news from Sweden, makes out a strong case in favour of the protective powers of B C G

B C G vaccination is now being carried out on a huge scale throughout the world In this country its use is still limited to certain groups of people thought to be exposed to the greatest risk of infection These favourable reports have prompted further discussion about whether it should be used more widely and to what sections of the population it should next be offered The discussions are always concerned with groups and categories, such as infants, "school leavers," and National Servicemen, little is heard on the question of whether B C G should be made available to individuals At present, a child who is not a "contact" cannot be vaccinated, however much the parents and the general practitioner desire it without reference to a chest physician B C G vaccination in this country has rightly been judged as a matter for planning and strict control, but there now seem good reasons for lessening control, while preserving the general plan of campaign

SEROLOGICAL INVESTIGATIONS

Complement-fixation Tests

The specimens of serum from the 8 patients were negative when tested against lymphocytic choriomeningitis and mumps antigens. The leptospiral agglutination tests were also negative.

Neutralisation Tests

The newly isolated strain of Coxsackie virus was used in these tests as a dilution of mouse-tissue suspension which, after being mixed with an equal volume of serum, contained about 100 L.D.$_{50}$ of virus.

In view of the increase in neutralising antibody titre against a strain of Coxsackie virus, found in sera from 4 patients, similar tests were made with sera from 3 of the inoculated monkeys (table V).

Monkey no. 1, inoculated with the stool suspension (case 1) containing the newly isolated strain of Coxsackie virus, had developed neutralising antibody against this virus. Its excreta were not examined for the presence of the virus. The sera from the 2 other monkeys showed no evidence of the development of a significant amount of neutralising antibody.

DISCUSSION

The admission to hospital of more than 100 patients with meningo-encephalitis, mainly within a comparatively short period during the summer of 1951, was unusual. A tentative diagnosis of non-paralytic poliomyelitis was encouraged by the simultaneous occurrence of cases of paralytic poliomyelitis. Later the disproportionately small number of patients with paralysis made this diagnosis less likely to be correct. In view of the benign nature of the illness it is probable that many more patients were treated at home.

The main features were a sudden onset, with pyrexia of variable duration up to two weeks and a biphasic pattern in some patients. There were severe headache, vomiting, cervical and spinal stiffness, occasional diplopia, and sometimes delirium or stupor. A positive Kernig's sign was not always obtained. The course of illness was uncomplicated, and recovery was complete. The C.S.F. in 90 cases showed a pleocytosis of 10–1000 cells per c.mm., with counts of 10–200 in most patients. Lymphocytes were the preponderant cells, but polymorphs sometimes predominated. Often the protein content was slightly increased. In about 10% of patients changes in the C.S.F. were noted only at the second time of testing, and the other patients, although clinically identical, showed no abnormalities.

Besides poliomyelitis, the clinical picture of mild neurotropic infection could have resulted from other infections—e.g., lymphocytic choriomeningitis, mumps, and leptospirosis—but the occurrence of so many cases distributed over a fairly wide area within a short time and without other distinguishing features rendered these infections unlikely for the group as a whole. Laboratory tests showed that sera from 8 patients were negative for lymphocytic choriomeningitis, mumps, and leptospirosis. Of stools from 7 patients which were investigated, a strain of poliomyelitis virus was isolated only from the patient with paralysis, an experience similar to that of Silverthorne et al. (1951). This has been found to be of the Leon type. A strain of Coxsackie virus was isolated from the stool of 1 patient out of 8 investigated, and it was found to be similar to the strains of Coxsackie virus isolated earlier in 1951 from an outbreak of febrile illness in a children's home near Coventry (Kenyon et al. 1952). In that outbreak strains were isolated from all 5 patients investigated, and in view of those findings the isolation of only one strain was initially thought to be a chance phenomenon unrelated to the illness under investigation. Further, no case of aseptic meningitis was observed during the outbreak in the children's home. Although our knowledge of these viruses is very incomplete, it has been found (Bury and Tobin 1952) that a single strain of Coxsackie virus may give rise to different clinical types of illness. Conversely, immunologically distinct strains of Coxsackie viruses may give rise to a similar clinical type of illness. Whether the excretion of virus differs with different illnesses or whether it occurs intermittently was not investigated. Subsequently it was demonstrated that sera from 7 out of 8 patients had neutralising antibody against this strain of virus, a point in support of its wide distribution throughout the Coventry area. During the course of illness no increase in neutralising antibody was found in 2 patients, 1 of whom had poliomyelitis. A slight increase occurred in case 8, who was admitted to hospital with scarlet fever and subsequently had mild encephalitis. A significant increase in antibody occurred in 4 patients, including case 1, from whom the strain of virus was isolated, and also in monkey no. 1. Sera from monkeys nos. 2 and 3 showed no significant amounts of neutralising antibody against this strain of Coxsackie virus.

In the absence of other known causes, and in accordance with practice, it may be accepted that, as a significant increase in neutralising antibody titre against a strain of Coxsackie virus occurred during the course of illness in 4 patients, this virus was a link in their infection. Of the remaining patients 1 had poliomyelitis and 1 had possibly a mild post-infective encephalitis. In 2 patients, 1 of whom had no changes in the C.S.F., a definite diagnosis was not made, but the possibility of infection by an unidentified organism has not been excluded.

It is hoped that the sera from the 8 patients will ultimately be tested for neutralising antibody against the three types of poliomyelitis virus.

Possibly some of the patients in this widespread occurrence of benign neurotropic illness were infected with a Coxsackie virus, but the problem remains whether or not the illness was, for the most part, provoked by a single ætiological agent, or whether there were several factors involved. Further investigation is essential before the ultimate rôle of the Coxsackie viruses and the part played by the poliomyelitis viruses are decided.

SUMMARY

112 cases admitted to hospital in 1951 with a benign meningeal or meningo-encephalitic illness, of whom 90 cases had an abnormal C.S.F. cell-count, are reviewed.

Virus investigation of specimens from 8 patients was undertaken. A strain of Coxsackie virus was isolated from 1 patient with mild meningo-encephalitis. In this patient and in 3 others increased neutralisation of this virus was observed in samples of serum obtained in the convalescent stage of illness. No increased neutralisation was observed in 3 patients, including 1 with paralysis. A strain of poliomyelitis virus was isolated only from the patient with paralysis.

Serological tests for lymphocytic choriomeningitis, mumps, and leptospirosis were negative.

Although the small number of virological investigations prohibits any general conclusion on the group as a whole, the possibility exists that a Coxsackie virus may

of pharmaceutical chemists first passed the minor examination, but since the introduction of university degrees in pharmacy, graduates have obtained this higher title by way of a greatly modified examination In practice, however, no one outside the profession realised that any distinction or difference existed Recently the Pharmaceutical Society ceased to examine at the "chemist and druggist" level, so the holders of this title now form a dwindling group The Pharmacy Bill, a private member's Bill now before Parliament, seeks to place all pharmacists on the register of pharmaceutical chemists If this becomes law, the present chemists and druggists will receive the title of "pharmaceutical chemist" by way of bonus Perhaps the existing holders of this qualification will feel they have suffered some loss of status and they may wish for a distinctive title as a sign of the standard they have attained

The century-old Act not only prohibited the Pharmaceutical Society from conducting examinations in medicine, surgery, and midwifery, but also debarred members of the medical profession from registering as pharmaceutical chemists, the new Bill will repeal the latter and retain the former provision Certain domestic matters of the society, including the abolition of the limit on the annual retention fee paid by members, are also covered by the Bill The Bill is sponsored by members on both sides of the House and seems to contain little that is controversial Incidentally, there is talk at the moment of establishing an examination in practical pharmacy for unqualified assistants, but it is to be hoped that this will not lead to a repetition of history and a demand for legislation to recognise a new class by statute

MEDICINE AND GEOGRAPHY

ORGANISED scientific collaboration between the different countries of the British Commonwealth is one happy result of the late world war Representatives of the Medical Research Council, Department of Scientific and Industrial Research, Agricultural Research Council, and Commonwealth Agricultural Bureaux have met regularly in London since 1946 with scientific representatives of Canada, Australia, Southern Rhodesia, South Africa, India, New Zealand, the Colonies, and latterly also Pakistan and Ceylon, to see what can be done to improve the exchange of scientific information and of specialist scientists, and how national laboratories can work for the benefit of the whole Commonwealth or share in international research The fruits of this combined approach include an index of English translations of foreign scientific papers, a book listing inter-Commonwealth postgraduate scholarships in science, maps of the prevalence of insect and fungus plant diseases, and the coördination of culture collections of micro organisms two reference laboratories of the Public Health Laboratory Service at Colindale (dysentery and food-poisoning) now work for the whole Commonwealth, with the exception of Canada These and other achievements are recorded in the report, just published,[1] of a special Commonwealth conference held in Australia last year

On the whole this scientific liaison work is for the benefit of official science, and relatively little is of medical import, but geographical anthropometry—the study of the normal physical standards of inhabitants of different countries or of different tribes in a single country—is proposed as suitable for research by collaboration throughout the Commonwealth This not only is essential for defining where disease begins, but may also prove a good test of the value of somatotyping and similar attempts to classify human physiques It seems a pity that the conference turned down a proposal to study geographically the prevalence of dental caries—apparently because this would be better investigated on a fu international scale The Commonwealth is large enoug for useful studies on the geography of many disease- and to wait till, say, the World Health Organisation ha money for international research of this sort and ca persuade its member nations to collaborate may be t wait a very long time The American Geographica Society has already begun to publish maps of th distribution of diseases[2] and how this is changing wit the years, and Sigerist[3] has discussed the kind o useful work to be done Research on this subject ca only be by international collaboration, and the Briti Commonwealth Scientific Conference ought to conside further how it might be promoted—for instance, b coordinating the work of national health department on the notification of disease

RUPTURE OF THE BLADDER

THE early diagnosis of intraperitoneal rupture of th bladder may be difficult Moreover, Negley[4] emphasise its importance by drawing attention to the danger o spread of infection, he found that the operative mortalit within the first twelve hours was 11%, it rose to 22% after twelve hours, and to 43% by the second day Various tests for the earlier diagnosis of this condition have been suggested and tried Recently, Cipolla and his colleagues[5] reported that in dogs a 0 5% solution of fluorescein was not absorbed from an intact bladder, but was readily absorbed from the peritoneal cavity and could be detected later in the blood-stream Similar results were obtained in experiments on human beings The authors suggest that in every case of suspected rupture of the bladder a 10 ml specimen of blood should be taken, and then 100 ml of a 0 5% solution of fluorescein passed through a urethral catheter into the bladder The control serum is compared with three specimens of serum removed at intervals of five minutes, the presence of fluorescein confirms the diagnosis A tear in the bladder may be plugged by omentum and the perforation may not be detected by other tests In dogs, Cipolla et al found that less fluorescein was absorbed when the tear was plugged by omentum than when it was open to the peritoneal cavity, and they suggest that this finding may be used to distinguish between a ruptured bladder which is sealed with omentum and one which is not

DIAGNOSIS OF MYASTHENIA GRAVIS

BEFORE the introduction of neostigmine by Mary Walker in 1935 myasthenia gravis was usually diagnosed by observing the characteristic distribution of the muscles affected—the occular and bulbar muscles and proximal rather than distal limb muscles—and by the history of diurnal fluctuations as well as remissions and relapse over months or years The greatest difficulty arose in patients with an unusual mode of onset, those with no tendency to remission, and those who in an early stage of the disease showed no physical signs and might be diagnosed as hysterical

Neostigmine, with its rapid action, was widely welcomed as a diagnostic agent The patient whose muscular power is not increased by a dose of 1 5 mg intramuscularly or 0 5 mg intravenously has not got myasthenia gravis—though the response varies widely from one patient to another Neostigmine may, however, also cause some temporary improvement in thyrotoxic myopathy[6] [7] and in dysphagia due to early progressive bulbar palsy Moreover, it has to be used with some care, and always with atropine (0 6 mg) because of it-closely round it. The steel cylindrical part has a mica window, so that the loop is visible while being flamed. The metal window-frame is bolted to the cylinder and can easily be removed to allow the mica to be replaced. A slit 1·5 × 4·5 cm. admits the loop for flaming. The top consists of a larger rimmed metal plate enclosing the cylinder, and a smaller one, 2 cm. below, enclosed by it; both have numerous ventilation holes, and the lower plate baffles the holes in the upper. Extending down 4 cm. from the upper plate is a small vertical baffle which helps to prevent the flame from escaping through the slit; when the apparatus is assembled, this baffle lies immediately within the slit, overlapping it slightly.

Reviews of Books

Rose and Carless' Manual of Surgery

for Students and Practitioners. 18th ed. Editor: Sir Cecil Wakeley, bt., k.b.e., c.b., ll.d., m.ch., d.sc., f.a.c.s., president of the Royal College of Surgeons of England. 2 vols. London: Baillière, Tindall, & Cox. 1952. Pp. 1471. 63*s*.

It is nearly ten years since the last edition of "Rose and Carless" appeared. In all its long history this is perhaps the most notable edition, for the book has been transformed and almost entirely rewritten. In accord with modern trends the special sections on pathology and bacteriology have been discarded, and collaborators have been brought in to deal authoritatively with the various divisions of surgery which have become specialties. The result is a textbook which reflects accurately the best modern English practice. The editor has been happy in his selection of authors. There is an evenness in presentation rarely found in multiple-author books.

One of the greatest difficulties in compiling a textbook for the undergraduate is to decide how much knowledge he can be reasonably expected to acquire: it is very easy for a specialist's judgment to err on the side of demanding more than the average student should be asked to pick up in the crowded years before qualification. This is a large book, and contains a formidable and rather frightening amount of knowledge for the man beginning his clinical work. But the alarm the student may feel when confronted with these two volumes will be lessened when he really dives into them; for the matter is presented well, clearly, and attractively. It is all so exciting to the newcomer to clinical surgery that he will soon find that the task of reading through this large book is very much lighter than at first sight it appears. As the surgery of the special senses and anæsthesia are included the ordinary pass student will need no special books on these subjects. The outlook is completely modern, and the illustrations and general make-up are excellent.

Psychiatry and Medicine

An Introduction to Personalised Medicine. Leslie A. Osborn, m.d., professor of psychiatry and acting director, Wisconsin Psychiatric Institute, University of Wisconsin Medical School; director of mental hygiene, Wisconsin Department of Public Welfare. New York and London: McGraw-Hill. 1952. Pp. 494. 64*s*.

This book sets out "to depict in clinical perspective the close relationship that is developing between psychiatry and medicine. It deals particularly with personal and interpersonal factors as they influence health and illness." Professor Osborn has had experience in the fields of general practice, geriatrics, and psychiatry, but his chief interest has been in clinical teaching on the lines of this book; as head of the department of psychiatry in the University of Buffalo School of Medicine, he had ten years' experience of teaching medical and dental students and social workers. His aim is to make us more aware of the patient as a complete person rather than as an aggregate of tissues and organs, and to inculcate a habit of mind that assesses the individual's constantly changing attitudes to his environment, to society, and to health or illness.

The first part of the book deals with theoretical concepts; the teachings of Freud as modified by Adolf Meyer seem to underlie the author's approach. The second part is concerned with practical applications of theory in clinical study and therapy, and a short concluding section considers preventive psychiatric treatment. An appendix gives some useful outlines of psychiatric and neurological methods of clinical examination, though even here the characteristic warning that no "system" can replace consideration of the individual heads the chapter.

The word "personalised" in the subtitle does not do justice to the sort of medicine which Dr. Osborn evidently practises; nor does it, to British ears, hint at the common sense and warm humanity of these pages.

Cancer in General Practice

Ronald W. Raven, o.b.e., f.r.c.s., surgeon, Royal Cancer Hospital: P. E. Thompson Hancock, f.r.c.p., physician, Royal Cancer Hospital. London: Butterworth. 1952. Pp. 265. 30*s*.

Though this book is intended for, and will be useful to, the general practitioner, its contents scarcely correspond to its title. "Cancer: a synopsis for general practitioners" would be more accurate. The chief physical facts about malignant growths occurring in the organs, systems, and regions of the body—incidence, pathology, spread, early and late symptoms, diagnostic procedures, treatment by surgery and irradiation, prognosis in terms of survival—are set out on an anatomical basis. There are illustrations—clinical, pathological, and radiographic—and a full bibliography, but no complete case-histories. Here and there a rule for investigation is laid down or a régime (in colostomy, for instance) is given in detail; but the outlook throughout is that of the surgeon, physician, or pathologist in a hospital investigating and treating disease processes, not that of the general practitioner essaying the often impossible task of early diagnosis and directing, sustaining, comforting, watching, and relieving the afflicted subject.

The problems raised by cancer in general practice are far more complex, formidable, and heartbreaking than is even hinted here. Some of them can be deduced from the grim facts given in the book, but few are directly faced and it is hard to believe that the authors have them clearly in mind. Perhaps even the implications of the advice given are not always appreciated. "Thus it is a rule to perform sigmoidoscopy on every patient who presents any abnormality of the anus or rectum. . . . No symptom, however trivial, should be overlooked and a complete examination should be made." Does this mean that every pruritus, superficial crack, pile tag, or anal hæmatoma must be sent to hospital for sigmoidoscopy? And if every abnormality *were* so referred would the complete examination indeed be made? Again, a thoughtful practitioner will surely require more evidence than is here adduced before urging a young woman with a stage-I carcinoma of the breast to accept double oöphorectomy as a supplement to mastectomy.

REABLEMENT OF HOUSEWIVES

A Lead from King's College Hospital

WHEN the housewife lays down her tools the effect on her family is much like that of a general strike on the nation at large. Ordinary pursuits are delayed and hampered, and special projects interrupted by the basic requirements of civilised living—meal-getting, house-cleaning, and washing-up. Reablement of men for industry, and of children for the schoolroom, has gone far, but the housewife disabled by rheumatoid arthritis, poliomyelitis, hemiplegia, or other disaster gets, if she is lucky, some physiotherapy and a few cheery words of encouragement. These are good in their way, but seldom fit her to get herself up, washed and dressed in the morning, or to do the vegetables, brush a floor, clean a saucepan, open a tin, or generally keep the home fires burning—even in a literal sense.

It is easy to plan a reablement programme from the wrong end, beginning with what the patient hopes to do in his job rather than with what he can immediately do for himself. Dr F. S. Cooksey, who is in charge of the physical-medicine department at King's College Hospital, points out[1] that though the personal activities of daily living are considered seriously in special centres for the limbless, the paraplegic, and the blind, they are ignored as far as the general run of disabled patients are concerned. His department offers a programme of reablement specially designed for housewives, beginning with the movements needed in dressing, feeding, getting in and out of a bath, using a toilet, and so on, and proceeding to all the skills required in getting a dinner.

USES OF OCCUPATIONAL THERAPY

The centre is small for the work it does. Rooms of various sizes have been partitioned off from a central space containing a desk for a secretary. One small room has been set aside for patients who need to practise dressing and undressing, and the walls are hung with a number of encouraging gadgets showing that this task can be greatly simplified. Men as well as women need this kind of help, so the gadgets include cuff-links which, having been put into the shirt in advance, expand on a spring and let the hand slide through the cuff, elastic shoe laces which can be left permanently in the shoes, a long handled shoe-horn which makes it easy to put the shoes on without stooping, and a device for sliding into nylon stockings, again without stooping, and also—which the wearer doubtless thinks even more important—without getting them snagged by the toe-nails. A tie, already neatly tied, is mounted on a spring like a bicycle clip, which can be snapped round the neck with one hand, and members of either sex, using a towel attached to the wall by a spring, can practise the motions needed for drying the back after a bath. Other encouraging exhibits are knives and forks with big handles, easily grasped by a partly paralysed hand, and spoons bent round at an angle so that they can be raised to the mouth by those whose elbows are fixed.

In a neighbouring workshop patients of both sexes are engaged in occupational therapy—but with a difference. They are making objects of use in the hospital (like rubber-covered rockers to be worn with plasters), and the tasks are assigned not on grounds of interest or variety but simply because they benefit a particular joint or group of muscles. Many patients, it seems, prefer sticking at a repetitive job which is benefiting a disabled limb to completing an object in which they have no particular interest. This preference became apparent when patients who attended rigorously at the gymnasium for directed physical training, and also put in strenuous hours doing unsupervised exercises in the department, failed to turn up for occupational therapy. When set to do a repetitive job which exercises the damaged limbs, they will attend regularly, without complaining of monotony.

THE KITCHEN UNIT

Some women are to be found in the general workshop, but they are few, for the chief workshop of a housewife is her kitchen, and the movements she needs to master are those she uses in getting the dinner. Dr Cooksey has therefore set up a kitchen in another room in the centre, but—again—a kitchen with a difference.

The working bench, with the sink in the middle, is flanked at one end by the oven and hot-plate of the gas cooker (which are separate and side by side) and at the other by a refrigerator (fig. 1). The hot-plate, and the middle shelves of the oven and refrigerator, are all on the same level as the top of the bench, and this is set at a convenient working height for a patient sitting in a wheel chair. The top of a stout trolley is also at the same height, and dishes can thus be slid from the bench to the trolley, and from the trolley to the oven, with no lifting. The trolley top is boxed in with stout wooden planks, partly to prevent things from slipping off it and partly so that

THE LANCET

LONDON: SATURDAY, FEB. 21, 1953

Facts about Nursing

Miss NIGHTINGALE had some clear notions about the nature of nursing; but without that penetrating mind to guide us we have fallen into confusion. The word "nursing," she said,

> "... has been limited to signify little more than the administration of medicines and the application of poultices. It ought to signify the proper use of fresh air, light, warmth, cleanliness, quiet, and the proper selection and administration of diet—all at the least expense of vital power to the patient ..."

In their welcome and unique report,[1] the Job Analysis Team of the Nuffield Provincial Hospitals Trust say that the modern tendency (clearly revealed in their survey) "is to regard 'the administration of medicines and the application of poultices' as the proper task of the skilled nurse, and to delegate the routine care of patients to less highly trained persons." This team, under the directorship of Mr. H. A. GODDARD, with Mrs. C. COLWELL as administrative assistant, Miss C. M. GRANT GLASS as nursing adviser, and Miss J. M. BLOMFIELD as leader of the field investigators, set out to give an exact and full account of the present duties of nurses in hospitals. The Working Party on the Recruitment and Training of Nurses,[2] it will be remembered, undertook a job analysis of the daily routine of 36 student nurses and 3 pupil midwives, and of a smaller number of sisters, staff nurses, assistant nurses, and nursing assistants, for the purpose of establishing the time spent on domestic duties, the amount of repetitive work in the nurse's training, and the extent of overlapping between various training courses. The Trust's team have approached the task more comprehensively and in a different way, by keeping entire wards under continuous observation over a period of time.

12 general hospitals which were also nurse-training schools were selected, 9 of them former voluntary hospitals and 3 former municipal hospitals. In situation they were scattered over England and Scotland, 4 serving rural, and 8 urban or industrial, populations; and they ranged in size from under 200 to 1500 beds. The block system of training operated in 6, the weekly study day in 1, and the remaining 5 maintained the old pattern which requires the student nurse to interrupt her ward work for lectures, and do her reading after work, in the evenings. Only 3 hospitals had introduced the three-shift system for student nurses: the remainder used the two-shift system with a spell of split duty during the day.

In these 12 hospitals the observers watched 26 wards on a minute-to-minute basis, noting everything that was done in them by all grades of staff (including orderlies, porters, and ward-maids), day or night, over a period of a week.

Two findings seem to us outstanding: almost three-quarters of the time spent on nursing duties in these wards was contributed by student nurses; and in most of these hospitals nursing was being done with inadequate equipment. The first point is perhaps less of a surprise than the second.

A contrast is evident between the medical, and particularly surgical, equipment in our hospitals and the equipment of the wards. Bedpan sterilisers have rarely been installed, which means that student nurses waste time daily in cleaning and disinfecting bedpans; as heated racks for the cleaned pans are equally scarce, students waste time and fuel daily by warming them with hot water before taking them to patients. Trolleys are often so scarce that it is impossible to keep them laid for any special purpose (such as blanket bathing), and time is therefore wasted in laying trolleys afresh for every purpose. The research team saw no bedpan trolleys at all, though in one ward the nurses had improvised them from linen containers. One hospital had provided a wire carrier for urinals. Only one bread-cutting machine was seen on a ward, and it was out of order; the hygienic idea of using sliced wrapped loaves does not seem to have penetrated to our hospitals. Three wards did their sterilising with a fish-kettle on a gas-ring, and two of them had no means of sterilising bowls other than by flaming with methylated spirit. Bedpans and wash-bowls were often exceedingly scarce, some wards having as few as 7 wash-bowls for 37 patients or 5 bedpans for 28 female patients; only three wards had more than 8 screens to a ward, and some had only 4, which meant that screens had often to be dragged or carried the whole length of the ward. None of the wards studied had substituted curtains for screens. A shortage of matches was the cause of many wasteful journeys to and fro with a taper.

It is customary just now to talk about economising our nursing-power: one simple way to do it would be to provide nurses with the tools of their trade in adequate quantity. How is it that matrons—masterful women in other respects—have failed to make themselves felt over this essential preliminary measure? And why have the medical staff—and especially surgeons, who are able campaigners for their own tools—not seen to it that their nursing teams are properly supplied?

Equipment apart, nurses are much hampered by the bad design of wards. A bathroom or sluice room placed at the end of a ward, instead of in the middle, may mean a walk taking 26 seconds each way when a bedpan has to be fetched and removed. Wash-basins may be equally badly placed at one end only of a ward. In one modern hospital studied the sterilising-room had no running water, and jugs had to be brought from the kitchen; and staff cloakrooms may be at a considerable distance from the ward. If bad structural design is a burden that probably must be borne for the time being, there is comparatively little expense in putting extra taps and wash-basins—or even water-closets—in sites where experience has shown them to be most needed.

Nursing is not the only work done in a ward: in fact, only about 60% of the time of the staff is spent on it. Nearly a quarter goes on ward organisation, and about a sixth on domestic work. The observers found that domestic work was done very largely by domestic staff, and that in most cases the student nurse was not required to do an excessive amount of it. Everyone will be glad to know that this perennial blister has been pricked at last. On the other hand the training needs of student nurses were regularly subordinated to administrative necessity, and the amount of time spent on teaching them in the wards, the team say, was negligible. "The highest figure recorded was 11 hours in the week, and the lowest 7 minutes." These figures represent the sum

[1] Ann phys Med 1952 1 120

some days œdema may be found. Examination of the chest most commonly reveals restricted movements and suppressed breath-sounds with scattered crepitations and occasionally conspicuous rhonchi. The sputum is purulent, and may have only recently become so. The temperature may be normal or moderately raised. Because of the added sounds in the chest and the manifest severity of the illness bronchopneumonia is often diagnosed; but radiographs seldom show consolidation. The arterial blood sample will have diminished oxygen saturation and raised carbon dioxide content and tension.

The diagnosis of cor pulmonale applies to those patients who have raised jugular pressure or œdema; this is a complication, common but not inevitable, of the disorder common to all—acute respiratory insufficiency. Usually in these patients moderate emphysema or other widespread disorder of pulmonary function has been suddenly aggravated by bronchial infection. How the infection, without necessarily extending into the alveoli, causes this abrupt functional deterioration is unknown. Bronchiolar congestion or constriction increases the work of breathing in some but not all of the patients; the fever is seldom great enough to provoke a large increase in oxygen needs; and one is led to suspect that the infection has in some way disturbed the distribution of pulmonary blood-flow.

The patient appears desperately ill; but, unless he was previously in heart-failure, he will probably recover. Because the spontaneous improvement may be as dramatic as was the onset, it is easy to overvalue any treatment. Morphine, sometimes given under the impression that the patient has left ventricular failure, may prove rapidly lethal. Intravenous digitalis and venesection (tempting because of the bulging veins) are also best avoided. Chemotherapy, however, is indicated, and fortunately penicillin is still usually effective. Isopropyl adrenaline, inhaled in a spray, will often relieve bronchiolar obstruction, and should be tried if the nature of the respiratory efforts suggests increased airway resistance. Arterial anoxæmia—the most serious consequence of the impaired respiratory function—can be corrected by increasing the oxygen content of the inspired air. This is most conveniently done by means of a tent; and by maintaining a good flow it is nearly always possible to restore the arterial saturation to a safe level. At best, however, this leaves unaltered the hypercapnia and respiratory acidosis, which unfortunately may sometimes be aggravated. This is because the more severely affected patients have modified their chemical respiratory drive and have come to rely on anoxia as the main respiratory stimulus. When the anoxia is relieved by breathing oxygen the ventilation falls and carbon dioxide retention is increased; and this can lead to headache, drowsiness, and even coma.[1] The reasonable way to counter this development is to maintain or increase ventilation. BOUTOURLINE-YOUNG and WHITTENBERGER[2] first reported favourably on the use of a respirator; and STONE et al.[3] have described four cases treated by this means: three were treated successfully with a Drinker respirator, and the fourth with an intermittent-pressure device. STONE et al. evidently feel that the respirator was an important factor in the patients' recovery, but most of those who have tried this treatment are likely to remain unconvinced. The Drinker respirator, designed for a paralysed patient, is far from ideal: the patient feels congested and dislikes lying flat; he probably has difficulty with sputum and is much alarmed if head movements are restricted. Because of his mechanical disabilities high pressures must be used to maintain a reasonable tidal air, and these cause uncomfortable movement of the neck seal. Moreover with a restricted tidal air high respiratory rates are needed, and these the standard motor cannot supply. Nor does any commonly available respirator seem much better. Possibly "electrophrenic respiration"[4] or a really effective respiratory-stimulant drug may prove preferable. At present the mechanical augmentation of ventilation in this type of respiratory insufficiency, in contrast to that due to muscular weakness, remains a therapeutic tour-de-force which can be effected if the patient can stand it.

In all this it is important to keep a sense of proportion. Most patients with acute respiratory insufficiency manifestly benefit from oxygen therapy despite some rise in carbon dioxide tension. Only a few patients become comatose or develop other serious troubles, and with these it is always possible to moderate the oxygen therapy to attain the best compromise. All who treat such patients should be aware of the possibility of respiratory depression, but patients must not be allowed to die of anoxia because of an exaggerated fear of carbon dioxide poisoning.

B.C.G.

IN 1922 WEILL-HALLÉ tried to protect children against tuberculosis by giving them the attenuated strain of tubercle bacilli produced by CALMETTE and GUÉRIN. During the next 25 years the vaccine was used extensively in many countries. Much work was done on its preparation and properties, its ability to induce tuberculin skin-sensitivity, and its alleged production of immunity to tuberculosis. But by 1947, when vast campaigns of vaccination were started by the International Tuberculosis Campaign, little precise information about B.C.G. was available, and it soon became clear that scientifically controlled studies were urgently needed. The Tuberculosis Research Office of W.H.O., with the collaboration of the Danish State Serum Institute and the International Tuberculosis Campaign, began a series of investigations into some of the basic problems; and the research office has now produced a monograph[5] which contains not only the reports of the separate investigations, many of which have already been published, but the complete quantitative data on which they are based. It is a valuable record of carefully planned and executed international research. There is no method of detecting or measuring immunity to tuberculosis produced in an individual by B.C.G. vaccination. The local reaction and the induced skin-sensitivity to tuberculin have generally been regarded as guides to the effectiveness of the vaccination, although CALMETTE himself considered

Annotations

INFLUENZA 1953

Disastrous floods and fogs have made this one of the worst winters for a long time; and influenza, making its biennial attack in this country, has added to our difficulties. But, in general, influenza has so far been mild. On its previous visit, two years ago, the influenza-A virus swept rapidly through the country, and in the first month of that epidemic there were nearly 5000 deaths from influenza. In the present epidemic the deaths from influenza have climbed slowly, and during the same period there were rather less than 600. Once more, deaths have been most numerous in elderly people—about 90% of those who have died were over the age of 55. A curious feature of this year's epidemic is that the incidence of influenza has been very much greater in the south of England than in other parts of the country; but perhaps that is simply a reflection of the higher incidence in the north during the 1950–51 epidemic. Some idea of the size of the epidemic comes from the claims for sickness benefit received by the Ministry of National Insurance; about 100,000 claims in excess of normal were recorded for the week ending Feb. 3, and most of these claims were probably the result of influenza.

At about the same time as the epidemic appeared in this country, sharp outbreaks were reported from France, Germany, and the U.S.A. Slightly earlier there was a severe epidemic in Japan, and lesser outbreaks have since been reported from Scandinavia, Finland, Holland, and Switzerland. Detailed laboratory and epidemiological observations must be completed before the source or sources of this year's influenza can be identified or the method of spread traced. Preliminary laboratory reports indicate, however, that in all the countries involved A-prime viruses have been recovered. Those isolated in this country show an antigenic similarity to strains recovered this year in the U.S.A., Japan, and Denmark, and also to the Scandinavian subtype which was partly responsible for the European epidemic of 1950–51. On the other hand, strains from France and Switzerland seem to resemble the Liverpool subtype which was also prevalent in 1950–51. It seems, therefore, that this year's epidemic had at least two foci of origin.

When the spring has chased these troubles away, the lessons of this year's epidemic will be clearer. In particular, the results of the influenza vaccine trial, organised by the Ministry of Health and the Medical Research Council, and of the epidemiological investigations of the World Health Organisation influenza programme, will be awaited with great interest in the hope that we shall be able to look forward to our next encounter with the virus with greater confidence.

DETERGENTS

The domestic use of detergents has increased enormously, and some of the results are causing concern. Mostly these agents are products of the petroleum industry; they are paraffin-chain salts, their long hydrocarbon chain having an electrolytically dissociated group at or near the end. They thus have strong surface activity which favours the penetration of water into the interstices of fabrics. They also exercise a powerful emulsifying action on greasy dirt; the film on the threads of cloth is rolled into loosely adherent globules which are easily detached by agitation and can be rinsed away.[1] In the home detergents are used, as well as for laundering clothes, to wash dishes and utensils; and in industry they are used for various degreasing processes. They also find a proper use in dermatology as emulsion bases and in antiseptic shampoos and the like. The domestic detergents foam readily and are apt to be judged by this quality. Foam, however, though it breaks up the oil and mechanically assists removal of dirt, is not necessary for detergent action, which may be little reduced by the addition of antifoaming agents.[2]

Detergents prove harsh to some skins, and may even cause dermatitis; they may act as primary irritants or may produce sensitisation. Their action may be partly due to their defatting and drying effect, which may aid the penetration of other irritants or aggravate constitutional skin disease. As Hodgson[3] points out, however, these agents are a valuable aid to the housewife, who soon learns which brand, if any, she must avoid. The commercial firms are aware of the danger, and before marketing their products usually submit them to immersion and patch tests on the human skin.

When the detergent leaves the kitchen sink, other problems arise. At the sewage works it is usual, especially on Tuesdays, to find that the agitation in the aeration tanks has produced a surface layer of foam as much as six feet deep. The narrow service "roads" between the tanks are slippery and dangerous; and huge masses of foam are liable to be whipped off by the wind, perhaps carrying pathogens and certainly a potential danger to car-drivers, on whose windscreens they may alight. In America such masses of foam are believed to have accounted for some "flying saucers." How far detergents interfere with the biological processes of sewage purification is not fully known; but they are not removed by present methods of treatment and therefore reach the effluents and the rivers into which these may discharge. River and harbour boards are concerned about the possible effect of these agents on fish or on the food of fish. Further, if the river should be a source of water-supply, the water undertaking is perturbed about the possible effects of the continued presence of detergents on the purification plant and on consumers.

There is no simple answer to this problem. The use at sewage works of water-sprayers or of chemicals with an anti-foaming action has been suggested. These, however, would increase the cost of sewage treatment and might bring other difficulties in their train. Workers in the U.S.A., who have longer experience of the trouble, have so far not found a solution. Clearly there is urgent need for research, in which we hope that the authorities and scientists interested will have the full coöperation of the manufacturers.

ONE REGISTER FOR PHARMACISTS

Unlike medicine or dentistry, pharmacy has two statutory registers, and consequently the term "registered pharmacist" includes the two groups, "pharmaceutical chemists" and "chemists and druggists." The reasons for this apparent anomaly lie in the history of the profession. The first Pharmacy Act, passed in 1852, sought to prevent ignorant and incompetent persons from assuming the title of, or pretending to be, pharmaceutical chemists or pharmaceutists or members of the Pharmaceutical Society. Accordingly the Act directed that a register of pharmacists and their assistants and apprentices should be established and maintained. Seventeen years later further legislation permitted assistants to become "chemists and druggists," entitled to sell and supply poisons, so that for over eighty years there have been two registers of people with these privileges.

Pharmaceutical chemists form less than one-tenth of the membership of the Pharmaceutical Society (membership of the society has been coextensive with registration as a pharmacist since the Pharmacy and Poisons Act, 1933, became law). They have had no advantages, apart from that of title and the benefits of having reached a higher educational standard. Formerly, the majority help housewives with damaged hearts to find easier ways of doing their work Some general advice on planning the work so as to walk and reach as little, and to sit as much, as possible is followed by photographs and descriptions of a simplified kitchen Tools are hung on hooks, within easy reach of the housewife sitting at the bench, and at the sites where they will be most often used Materials and supplies are placed on shallow shelves in the same vicinity Thus at the "mix centre"—the bit of bench which the housewife uses for pastry making and mixing ingredients—the rolling-pin, spoons, measures, sugar and flour, dried fruits, flavouring agents—are on shelves facing the sitting housewife, all within easy reach, and the pastry bowl is kept on a shelf fixed on the inside of the cupboard door which swings open at her knee. The sink is backed by shelves for detergents, and is flanked by the "vegetable centre," where the day's vegetables are stored in a wire basket at the back of the bench and the necessary knives and parers hang in rows beside the cooking pans This part of the bench is pierced with a large hole closed by a chromium lid which fits flush with the surface When the lid is removed the hole is directly over a tall rubbish-bin standing in the cupboard below, and vegetable parings are dropped straight through into it The can, like the pastry bowl, stands on a shelf on the cupboard door, and when the door is opened the can swings out with it and is easily removed for emptying

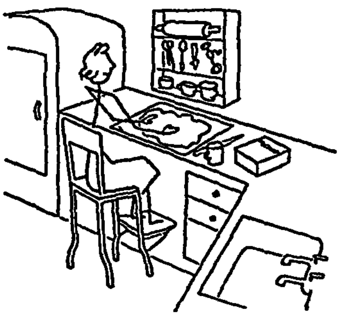
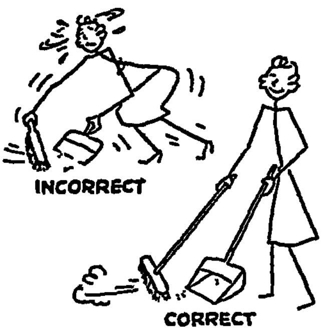
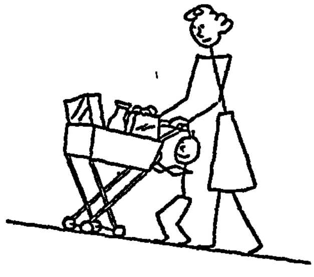
INCORRECT



CORRECT



The "heart" housewife, like Dr Cooksey's patients, has a trolley for moving plates and dishes, but a very light one It, too, is the same height as the bench, the oven, and the top of the cooker Some cupboards in this kitchen are partitioned vertically to hold baking tins and other objects often stacked inconveniently in piles Everyday china is stored at the right of the sink in a set of shelves open at both sides, like a hatch, thence it can be transferred to the trolley with little effort Tinned foods and other things used first at the stove (like gravy-browning) are stored, one tin deep, on shallow shelves near the cooker Small pieces of equipment used for many purposes (like measuring spoons) are duplicated and kept in the various sites where they will be needed Long-handled brushes and dustpans save the housewife from stooping, and she uses dusting mittens (not so far current in England) which allow her to dust with both hands Her chair has wheels on the back legs, so that she can push it about like a barrow, and when she goes marketing she uses a shopping cart with a light frame and canvas container to bring home her purchases.



The canvas shopping cart.

AMERICAN PLANNING FOR HEALTH

THE MAGNUSON REPORT

In December, 1951, President Truman announced that he had signed an executive order creating the President's Commission on the Health Needs of the Nation The major objective of the commission would be to make a critical study of total health requirements in the United States, both immediate and long range, and to recommend courses of action to meet those needs

Less than a year later, on Dec 18, 1952, the chairman of the commission, Dr Paul Magnuson, submitted the commission's report and recommendations, and concluded his letter of transmittal with these words "In all humility we think that this report lays the groundwork for men of good will to unite in a common effort to improve the people's health, the backbone of our democratic strength in a free world"

The report is in five volumes, of which the first embodies the commission's principles, major findings, and considerations[1]

To investigate and report on the health needs of 155 million people within twelve months is no light task by any standards, and it is first necessary to inquire as to the qualifications of the people who accomplished it

Dr Paul Magnuson is professor emeritus of bone and joint surgery at Northwestern University, Illinois The vice chairman, Chester I Barnard, is chairman of the National Science Foundation, and the commission includes Dean Clark, Lowell Reed, and John Grant Of the sixteen members, including chairman and vice chairman, six are medically qualified, two were dentists (including the late Ernest G Sloman), one, Marion Sheahan, is a registered nurse, and the remainder are laymen The lay interests are extraordinarily wide, with such people as Walter P Reuther, president, United Automobile Workers, Clarence Poe, president and editor, the *Progressive Farmer*, Elizabeth Magee, secretary, National Consumers' League, the president of the International Association of Machinists, Joseph C Hinsey, PH D, dean of Cornell University Medical College, and the president of Fisk University

METHODS

The commission first assessed, with the help of its technical staff, the total health resources of the country, and then set out to estimate the health needs of the American people Not surprisingly they found this the most difficult of their tasks It was accomplished by means of panel sessions, at which more than four hundred experts appeared (the official record of these panels runs to more than two million words), and by eight regional public hearings "at the grass roots," right across the continent from Philadelphia to San Francisco "The public outpouring at these hearings was so great that a number of them ran two or three hours beyond the scheduled closing time" In addition to individual panels, joint panels, and public hearings, monthly commission meetings were held lasting from two to six days each

Volume 1 of the report deals with all aspects of the subject under investigation—*population*, vital statistics, tendency to cause intestinal colic and, more rarely, vomiting.

---

[1] Building America's Health a report to the President by the [illegible] on the Health Needs of the Nation. [illegible] Vol 1 [illegible] Recommendations Washington 1952

Osserman and Kaplan [8] have described their experience with a new antimyasthenic substance as a diagnostic agent. This substance, edrophonium chloride (3-hydroxyphenyldimethylethyl-ammonium chloride) was given intravenously in a 10 mg. dose without atropine. Results comparable to those from 0·5 mg. of neostigmine were seen, with no unpleasant side-effects, in 15 myasthenics. The new drug has a brief action of less than an hour, and will therefore have no place in treatment. In the consulting-room and the outpatient department, however, it should prove useful because of the absence of side-effects and the fact that if a first injection gives a doubtful result a second, larger dose may be injected an hour later. Doses of up to 20 mg. are well tolerated.

HEPATIC BLOOD-FLOW

THERE is as yet no satisfactory simple method of determining the hepatic blood-flow in man. A reliable indirect method would be invaluable to the clinical scientist; direct measurements such as those made in animals are of course out of the question.

The methods now in use are based on the Fick principle, by which the volume of blood passing through an organ can be calculated from the difference in concentration of some arbitrarily chosen substance in the afferent and efferent blood. To make this calculation in the case of the liver, samples of blood must be obtained from the hepatic veins—by no means a simple matter. Several observers,[9] [10] however, have used this method with bromsulphalein as the test substance; and the average hepatic-flow in subjects without hepatic disease was 1 ml. of blood per ml. of liver substance per minute. A further serious drawback to this method has been revealed by having the catheter in different positions in the hepatic vein; this has shown that different areas of the liver differ in their ability to extract the dye. Thus it is almost impossible to obtain a true mixed hepatic-vein sample.

Dobson and Jones[11] have shown that the phagocytic activity of the liver for radioactive particulate matter injected intravenously gives a guide to the hepatic blood-flow; and thus the need for catheterisation of the hepatic vein is obviated. They showed in dogs, rabbits, mice, and rats that over 90% of an appropriate suspension of radioactive chromium phosphate was retained within the liver and spleen. Moreover the liver extracted more than 90% —i.e., hepatic venous blood contained less than 10% of the radioactive material that was present in portal blood. (Since almost all the blood passing through the spleen also flows through the liver, the phagocytic activity of the spleen does not significantly affect the calculation of hepatic blood-flow based on the rate of removal of the radioactive suspension.) It is therefore apparent that, at least in these animals, hepatic blood-flow could be calculated fairly accurately from the rate of removal of the intravenously injected test substance. After the material has been injected intravenously samples are withdrawn at short intervals to estimate the quantity still remaining in the blood-stream. From the time taken for this to fall to 50% of the initial value, the minimal hepatic blood-flow can be readily calculated. This figure is a minimal value because the calculation is based on the supposition that the liver removes 100% of the foreign particulate material brought to it. The correct figure is probably only 90%, and the true hepatic blood-flow is thus 10/9 times that calculated.

Owing to the undesirability of injecting radioactive material, Dobson and Jones have restricted their clinical study to cases in which such injections were given for therapeutic purposes. Three cases of malignant disease with grossly enlarged livers were investigated. Owing to the obviously pathological state of the liver, the values obtained for hepatic blood-flow were probably grossly abnormal; these values ranged from 0·7 to 1·7 volumes of blood per volume of liver per minute. The principle of the test does not, however, depend on radioactivity per se; and there is no reason why non-radioactive inert particulate material should not replace the chromium phosphate used in these experiments. All that is required is some substance that can be easily and accurately estimated in micro quantities. Alternatively a radioactive particulate substance could be used which has a much shorter half-life than 14 days—the half-life of the P^{32} used in the radioactive chromium phosphate. With such material the hepatic blood-flow and the factors influencing it could be safely studied in man.

WEATHER AND POLIOMYELITIS

POLIOMYELITIS keeps cropping up in the winter, but the great majority of cases arise in the summer and autumn. One unexplained exception to this rule, however, has been reported from Melbourne, where the three main poliomyelitis epidemics since 1937–38 have reached their peak between July and October—the coldest and wettest season of the year.[1] In New York State the ratio of summer to winter cases in a series of epidemics was 12 : 1, compared with 2·2 : 1 in Japan during the same period.[2] This suggests that degree of climatic difference between summer and winter may be an important factor in determining the seasonal distribution of cases; but it would be unwise to assume that the endemic poliomyelitis of Japan can be simply compared with the epidemic disease of the U.S.A.

In the United Kingdom the first great epidemic of poliomyelitis was in the summer of 1947, which was hotter than the average; and at the time it was widely believed that this might be a causal factor. Bradley and Richmond [3] have now studied the relation between temperature and humidity readings and the incidence of poliomyelitis in England and Wales during the six years 1947–52. The average weekly dry-bulb and vapour-pressure readings in London, Plymouth, Manchester, and Tynemouth were tabulated against the estimated number of people infected each week. These figures for infection were calculated by dating back the uncorrected weekly notifications by three weeks, in order to bring them as far as possible into line with the meteorological conditions at the time when the patients were likely to have been infected. The results are inconclusive; but they do confirm that poliomyelitis in these six years was definitely seasonal, the season each year extending from the 18th to the 42nd week. The rise in each year did not take place until a certain level of temperature and humidity had been reached; but these alone did not necessarily initiate the rise. The seasonal fall was even more independent of such meteorological factors. Moreover the incidence of poliomyelitis during the season was not clearly related to variations in temperature and humidity. The seasons with the lower average dry-bulb and vapour-pressure readings tended to have the lowest incidences of poliomyelitis; but this could have occurred by chance. It seems clear that other factors besides high temperature and humidity determine whether there shall be an epidemic of poliomyelitis.

DR. HAROLD BALME, consultant adviser on rehabilitation to the Ministry of Health and to the World Health Organisation and a former president of Cheeloo University in China, died on Feb. 13 at the age of 74.

commission's endorsement of the prepayment principle and Federal matching grants to States (on the basis of relative wealth and need), but emphasises the desperate need for prompt action among the rural population of America Dr Hinsey concurred in the financial recommendations only if free choice of health personnel and freedom of type of practice were maintained, and a system of remuneration mutually satisfactory to members of the health professions and the public could be devised

The United States has no unified central health department, and the report reveals some of the reasons for this They include opposition by the Veterans Administration and the Department of Defense, which fear the dangers to their medical services, and "the zealousness of some of its partisans to give this Department a bigger bite than it can possibly chew in its formative years" The recommendation is brief and to the point it is that "the Congress establish a Department of Health and Security" Dr Hinsey again dissented as he considered that the matter required further study Mr Graham and Dr Russel V Lee felt that there should be a Department of Health with cabinet status but had doubts on extending its function beyond health activities

SPECIAL PROBLEMS

The report next turns to special aspects of health service, including the expansion of programmes of disease detection, and especially multiple screening, a bold attack on chronic disease to be promoted by the health departments, and the development of home care services Research into mental illness must be given top priority, and prevention of accidents a high priority Also "less time should be spent on perfunctory annual examinations of school children as they are too often performed today," and more time devoted to careful health screening and follow-up

The report examines the special problems of industrial workers and rural people, including the deplorable conditions of migratory labourers The problems of ageing, the veterans, the rural Negro, and the Indians are all carefully considered and the difficulties of drafting doctors, dentists, and veterinarians into the armed forces (obviously a sore point) are recommended for further study

PROPOSED HEALTH COMMISSION

Finally comes the recommendations that

1 The Congress establish a Federal Health Commission

2 Comparable bodies be established in State and local communities

The Health Commission is to fill the rôle of constant critic and evaluator with an absolutely free hand, while the Federal health department would be primarily an administrative organ of government The health commissioners should receive no salaries, not more than half the members should be professional health workers, and no member should be an officer or employee of either Federal or State government The commission should have the power to hold public hearings, and should make an annual report to the President and the Congress on the health status and health needs of the American people, including recommendations for legislation whenever this is indicated

THE COST

As to the total cost of the recommendations, the Federal government at present spends just over 1000 million dollars each year on civilian health activities The health programme outlined in this report would require an annual Federal expenditure of approximately 1000 million dollars more

Parliament

Prevention of Misuse of Drugs

In the House of Lords on Feb 12 the **Earl of Onslow**, moving the second reading of the Therapeutic Substances (Prevention of Misuse) Bill, said that its main object was to empower the Minister concerned to regulate the use of new drugs This applied particularly to isoniazid, a cheap product, which at the moment did not come within the scope of the 1947 Act, and could, if used for self-medication, do great harm The other purpose of the Bill was to allow the Minister and his colleagues by regulation to permit the use of certain of these drugs particularly at the moment penicillin, in the feeding of pigs and table poultry

Lord **Amulree** thought that if penicillin was to be fed to pigs, it must be supplied by a veterinary surgeon, otherwise people might buy it for themselves He also suggested that the Royal Veterinary College should be consulted about any regulations to be made under the Bill when it became an Act Lord **Haden-Guest** was doubtful whether it was necessary to add the veterinary surgeons to the two well-qualified bodies—the Agricultural Research Council and the Medical Research Council—under whose advice the supervision of the giving of penicillin was to be

Replying to the debate, the **Earl of Onslow** said the A R C and the M R C were satisfied that penicillin fed to pigs in this form could do no harm The quantity was so small that it could not affect the consumers of the pig meat The penicillin would be fed in one of two ways, either in a compound food, where the makers would have to put on the compound a statement of what had been included in it, or in a special mixture—so diluted that it was impossible to extract the penicillin for use in other ways—which the farmer would then be able to mix in his own feeding-stuffs He was quite satisfied with the assurance that there could not be anything harmful in the admixture in the feeding stuffs for either poultry or pigs

QUESTION TIME

Health Services Charges

Mr **Arthur Blenkinsop** asked the Minister of Health the number and cost of prescriptions issued, dental treatment provided, and appliances issued, for which charges were imposed under the National Health Service Act, 1952, for November and December, 1952, compared with the figures for November and December, 1951 —Mr **Iain Macleod** replied The following are the figures for England and Wales

PRESCRIPTIONS

—	Number of prescriptions		Average cost per prescription	Total cost
November 1951	19,034,911	actual	46 02*d*	£3 649,880
December, 1951	17,815 111		46 58*d*	£3,457 607
November, 1952	17 439 000	declared by chemists	Not yet available	
December 1952	20 100 000			

These figures include prescriptions for appliances ordered by [illegible] and dispensed by chemists and prescriptions [illegible] and dispensed by chemists [illegible] number of prescriptions

DENTAL TREATMENT

—	1951		1952	
	Nov	Dec	Nov	Dec
	£	£	£	£
Number of completed courses of dental treatment under normal procedure (other than for the provision of dentures to which the 1952 Act charges do not apply) *	363,000	388,000	414 000	333,000
Number of courses for limited treatment provided under simplified procedure †	236,000	201 000	127,000	102,000
Cost to the Exchequer	950 000	1 000 000	850 000	700 000

* Less than half the courses given were subject to charges under the 1952 Act The remaining courses were started before June 1 or were for items of treatment to which the charges do not apply or were for the exempted classes of patients

† The courses for limited treatment, which consist largely of extractions of one or two teeth, usually cost under £1 and many patients may therefore be assumed to have had the treatment privately

patients who need support can grasp the sides firmly and use the trolley as a walking-chair (fig. 2). Patients working at the sink need never lift a kettle to fill it, for the taps are fitted with a swinging delivery pipe, of the type used in operating-theatre basins, which will fill a kettle as it stands on the draining-board. Moreover, the taps turn on and off by levers.

A flap which pulls out from the front of the bench is pierced with three circular holes, one of a diameter to take a pastry bowl, one to take a pudding basin, and one fitted with a gripping lining which holds jars firmly so that their lids can be removed with one hand. A square socket fixes tins of a standard size, for the same purpose. A clamp fixed to the bench behind the pastry bowl can be used to hold a variety of tools—a potato-peeler, an egg-whisk, a mincer, a grater, and others. The hemiplegic housewife is thus able to do with one hand many jobs which normally take two. Along an overhead track, running from end to end of the bench, a sling attached to a spring can be made to travel (fig. 1). A weak arm (damaged perhaps by poliomyelitis) which cannot work against gravity will often do much more when supported in such a sling (fig. 3). A bow-fronted cupboard at one corner of the bench is fitted with circular shelves which rotate round a pivot, so that there is never any need to reach to the back of a shelf, or take out half the contents in search of one elusive tin.

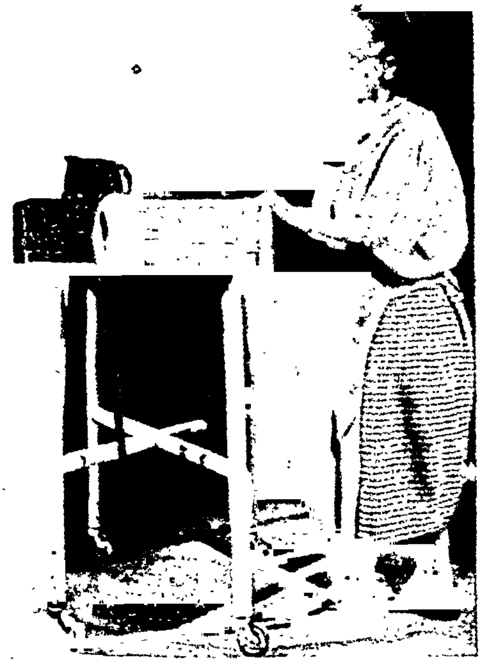

Fig. 2—The food trolley used also as a walking-chair.

The oven lights from a pilot jet when a tap is turned. Hot dishes are transferred to the trolley and wheeled to the table, where—since the table is usually the lower—a flap can be let down from the trolley to form a slope down which the hot dish is gently slid. Arthritic patients who find it difficult to sit, or to rise from ordinary chairs, are provided with stools with seats at the height to suit them, and with the seats sloping downward and forward. Such a stool, made to suit the individual in the hospital workshops, allows the patient to take the weight off her painful joints when working. Those who are not too steady on their legs find their confidence greater when using a safety-belt, clipped to the front of the bench by leash-snaps. In this very kitchen patients take it in turns to prepare the daily dinner eaten by the dozen or more patients, men and women, attending the reablement department throughout the day.

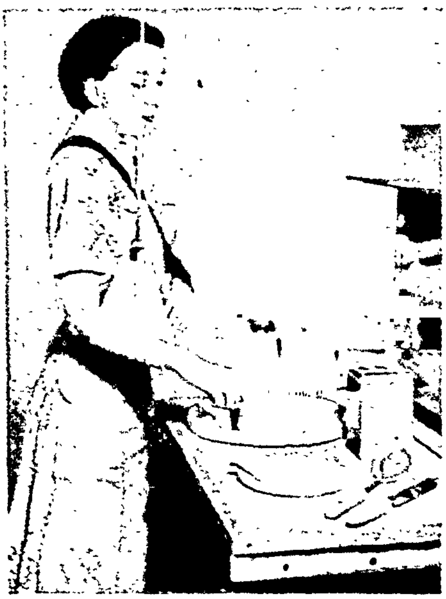

Fig. 3—Working with the sling which runs along an overhead track.

EQUIPPING THE HOME

Most of the equipment used is so simple that it can easily be copied in the patient's own home; and when the housewife leaves hospital the occupational therapist from the department goes to her home and discusses with her and her husband what she will need in her work—usually a board between cooker and sink, to save lifting, a board to steady bowls, a universal clamp for tools, and perhaps a trolley and stool. Most of these things are made by patients in the workshop and supplied at the cost of the materials used. A curtain-runner makes a good overhead track for a sling, and handrails are easily fitted in lavatories and bathrooms. If the family cannot meet the cost, the almoner helps to find ways of paying it. Recently[2] Lambeth Borough Council decided to make the necessary alterations for patients who live in their flats—a generous and sensible decision, for the time of everybody in the family is saved if the housewife is able to do her own work.

A DAILY CLUB

One need is still unfulfilled. Some men and women patients, too old or disabled to work, and often living alone, are allowed to go on attending the reablement department on two or three days a week, partly to continue with occupational therapy, and partly because they benefit from the company and activity. Dr. Cooksey would like to be able to establish a kind of club for such patients, outside the hospital though linked with it, where they could meet daily, take responsibility for the management, and cook the midday meal. Some of the disabled men, especially, would benefit by this arrangement, for it often happens that their wives, who could otherwise go out to work (and would like to do so, to relieve financial stringency), are obliged to stay at home to look after them. In such a club the disabled could look after and cheer each other. Such a reasonable project deserves success; and other hospitals would doubtless profit from the lead.

A Kitchen for Heart Cases

Hearts can be disabled as well as limbs. The American Heart Association has published a booklet[3] designed to put into the tank without loss of water or fish A satisfactory rise in temperature was recorded But darkness was falling and our patients had to go to bed The bottles needed refilling, if the fish were to survive There seemed to be no-one available to do this until our Night Sister, in common parlance, "blew in" Scorning the modified polar costume we were wearing, she retired to arrange her cap and cuffs, then, with electric torch held in her teeth, set off with the hot-water bottles, avoiding groaning and crashing trees, to the fish tank She was later reported to have been anxious lest she inadvertently crush one of the angel fish while inserting the fresh jars

CRI DU CŒUR

One gropes around in darkness, kneeling on the muddy road,
To fix the jack which always slips just as it takes the load
One prises off the dust cap and by sundry feats of strength
Loosens the nuts that fix the wheel, one gets it off at length
By further skill, but mostly force, one levers out the spare,
As like as not one finds it flat so pumps it full of air
And carries it with sighs and grunts and rams it into place,
Pausing but long enough to wipe a red and sweating face
One finds the nuts and screws them on—they must be screwed on tight—
But cannot find the dust cap which has vanished in the night
Repeating strings of awful oaths which one should not repeat,
Blackened with rage and oil and grime one takes the driving seat,
Drives off at speed but two miles on is horrified to find
The wheel so painfully removed was somehow left behind
A melancholy story—which impels one to inquire
Why has nobody invented an unpuncturable tyre ?

* * *

In a country where many things are changing rapidly, the Uganda Railway is still much the same as when Treves recorded his journey on it in 1910 True it has twice changed its name, but the average speed of its trains is still less than 18 miles an hour, which allows ample time to watch the game animals and the birds which use the telegraph wires as perches

But it is the stations which provide the greatest source of interest There the features of many different tribes may be observed, while the scanty clothing permits the observation of many pathological lesions The children are most easily studied, for many of them still wear no garments Umbilical herniæ are common, and others have pot bellies on which the outlines of enlarged livers and spleens can be imagined On our journey we saw one child with the typical gait of congenital hip dislocation and another with severe flexion deformities of the knees Many natives show scars in which pigment is lacking in comparison to the remainder of their skin, while the eye conditions would provide a feast of clinical material for the ophthalmologist. The garments of the men fail to conceal the fact that hydroceles are still common, as they were in Albert Cook's early days, while there are beggars with deformities which would require further investigation

Apart from these pathological conditions, the abnormalities wrought by tribal custom are interesting—the stretched lobes of the ears, the loop of which may be turned up and suspended over the apex of the pinna, or else left hanging down perhaps as far as the shoulder, the perforated lower lip of certain northern tribes containing a metal ornament, or the ala nasæ punctured to carry a ring Finally the custom of smoking a cigarette with the lighted end inside the mouth has to be seen to be believed

Certainly a fascinating journey, and I, for one, am glad the trains go no faster

* * *

Nature Note—The first spring greens of the season evoke the same sort of response from the salivary glands that daffodils do from the spirit Ours, though looking in the dish like a wreath for Primavera, turned out to taste of nothing in particular They smelt of nothing in particular too We were puzzled until we remembered it was because of the chlorophyll

Letters to the Editor

INTUSSUSCEPTION

SIR,—We feel sure that many will share our disagreement with your leading article (Jan 31) on intussusception In the past nine years 378 children with this condition have been seen in the children's department here, and it is from this experience in which we have collaborated that our comments are made

We agree that the pessimistic statement "clinical statistics on the efficacy of any particular form of treatment are seldom very reliable" has been true for many papers on intussusception, but it need not be so if the type of case, and method of treatment, are carefully defined From this point of view the term intussusception, by itself, does not take us very far For valid comparisons we must know the exact ages of the children in the series, the proportion of small-bowel, "boundary," and large bowel invaginations, and, above all, the duration of the symptoms when treatment was applied

When these factors are comparable we find that both surgical reduction, and enema reduction combined with surgery when necessary, will be equally successful provided the operator in each case is thoroughly experienced in the technique employed This proviso of course has important professional and administrative implications which we cannot take up here

As early as 1937 Hipsley,[1] using saline enema reduction as his first approach, achieved a mortality of 4% A comparison with those series managed by surgery which were available at that time, suggested the undoubted superiority of Hipsley's method A careful scrutiny of his paper, however, supplemented by personal inquiry, showed that the majority of his children were admitted within the first twenty-four hours of the disease This early admission also applied to the careful series using barium enema reduction under direct vision described by Nyborg,[2] and by Hellmer [3] On the other hand, our own mortality with surgical reduction has always been less than 4% for cases admitted within twenty four hours, - and in 1951 and 1952, for acute cases (i e, cases admitted in under five days) the over all mortality has been just over 1% An account by one of us (J D T J) of the children treated during this two year period is at present awaiting publication The reasons why the mortality has fallen from 10% to 1% over the nine years, seem to us clear and important Firstly, in 1944 (excluding chronic intussusception) only 31% of the children reached hospital within twenty four hours and 48% in forty-eight hours whereas in 1951 and 1952 the figures were 54% and 85% Secondly, operation is always preceded by the careful correction of shock and fluid loss Lastly—and this represents a significant change from our last communication on the matter in 1950 [4]—the surgery of intussusception is now confined to a small number of surgeons who are giving much of their time and thought to the emergency surgery of childhood in this hospital

This brings us to our second major criticism You say "there seems to be no particular advantage in the Mickulicz type of two stage exteriorisation procedure", but during 1951 and 1952 bowel resection was carried out in 9 children with acute intussusception with only 1 death Although we have not used the classical Mickulicz type of operation, all these resections were carried out by a two stage procedure Our reasons for favouring this method will be given in the forthcoming article already mentioned

We must also take issue with the phrase "the inconstancy of symptoms" We find that where careful

The hemiplegic housewife is thus able to do with one hand many jobs which normally take two. Along an overhead track, running from end to end of the bench, a sling attached to a spring can be made to travel (fig. 1). A weak arm (damaged perhaps by poliomyelitis) which cannot work against gravity will often do much more when supported in such a sling (fig. 3). A bow-fronted cupboard at one corner of the bench is fitted with circular shelves which rotate round a pivot, so that there is never any need to reach to the back of a shelf, or take out half the contents in search of one elusive tin.

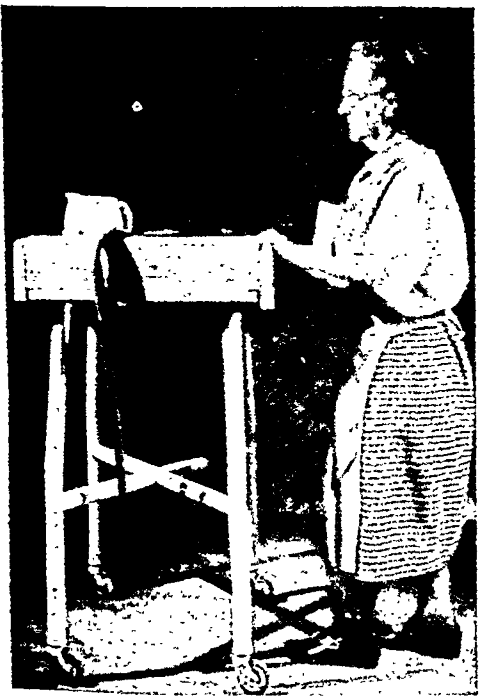

Fig. 2—The food trolley used also as a walking-chair.

The oven lights from a pilot jet when a tap is turned. Hot dishes are transferred to the trolley and wheeled to the table, where—since the table is usually the lower—a flap can be let down from the trolley to form a slope down which the hot dish is gently slid. Arthritic patients who find it difficult to sit, or to rise from ordinary chairs, are provided with stools with seats at the height to suit them, and with the seats sloping downward and forward. Such a stool, made to suit the individual in the hospital workshops, allows the patient to take the weight off her painful joints when working. Those who are not too steady on their legs find their confidence greater when using a safety-belt, clipped to the front of the bench by leash-snaps. In this very kitchen patients take it in turns to prepare the daily dinner eaten by the dozen or more patients, men and women, attending the reablement department throughout the day.

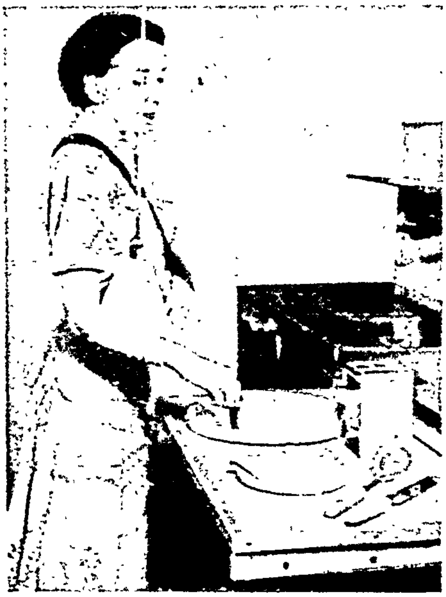

Fig. 3—Working with the sling which runs along an overhead track.

EQUIPPING THE HOME

Most of the equipment used is so simple that it can easily be copied in the patient's own home; and when the housewife leaves hospital the occupational therapist from the department goes to her home and discusses with her and her husband what she will need in her work—usually a board between cooker and sink, to save lifting, a board to steady bowls, a universal clamp for tools, and perhaps a trolley and stool. Most of these things are made by patients in the workshop and supplied at the cost of the materials used. A curtain-runner makes a good overhead track for a sling, and handrails are easily fitted in lavatories and bathrooms. If the family cannot meet the cost, the almoner helps to find ways of paying it. Recently[2] Lambeth Borough Council decided to make the necessary alterations for patients who live in their flats—a generous and sensible decision, for the time of everybody in the family is saved if the housewife is able to do her own work.

A DAILY CLUB

One need is still unfulfilled. Some men and women patients, too old or disabled to work, and often living alone, are allowed to go on attending the reablement department on two or three days a week, partly to continue with occupational therapy, and partly because they benefit from the company and activity. Dr. Cooksey would like to be able to establish a kind of club for such patients, outside the hospital though linked with it, where they could meet daily, take responsibility for the management, and cook the midday meal. Some of the disabled men, especially, would benefit by this arrangement, for it often happens that their wives, who could otherwise go out to work (and would like to do so, to relieve financial stringency), are obliged to stay at home to look after them. In such a club the disabled could look after and cheer each other. Such a reasonable project deserves success; and other hospitals would doubtless profit from the lead.

A Kitchen for Heart Cases

Hearts can be disabled as well as limbs. The American Heart Association has published a booklet[3] designed to

[2] *Manchester Guardian*, Nov. 22, 1952.

[3] The Heart of the Home. American Heart Association, 1775, Broadway, New York 19, New York, U.S.A. Pp. 28. 10 cents.

75%—will be completely denied this type of service *Theoreticians who do not realise the practical consequences of such an action may be compared with those who have in recent years exacerbated the problem of the care of the aged by decreeing that, as every aged person can have his own doctor and hospital services are free, there is no further need for the relieving officer or compulsory financial responsibility of relatives A similar devastating error was the cause of the partial collapse of the priority dental services, when dental attention was made available to all even though the priority dental services were given special mention in the National Health Service Act itself

Finally, as some of your correspondents have pointed out, in the interests of social medicine it is surely necessary that the family doctor should, as his name implies, look after all members of the family, and to introduce a special type of pædiatrician general practitioner who would remove the child from the care of the family doctor would be a most retrograde step

COLLEGE OF GENERAL PRACTITIONERS

SIR,—The undersigned general practitioners met informally on Jan 14 to discuss the implications for Irish doctors of the report of the General Practice Steering Committee[1] and the subsequent foundation of the College of General Practitioners in London

It was unanimously agreed that these developments were of considerable importance and that a meeting representative of all general practitioners should be called in the near future in order to have the fullest discussion on the subject and to decide upon a unified line of action Through the courtesy of the authorities of University College, Dublin this meeting will be held in the college on March 15

This promises to be the most important meeting ever held in this country in relation to general practice We hope that it will be attended no matter what the personal inconvenience not alone by all those already working in this branch of medicine whether as dispensary doctors, private practitioners, or in any other circumstances but also by the newly qualified men and women intending to make general practice their career

It may be useful for those attending if some of the points raised at the preliminary discussion are mentioned here Irish practitioners have four choices in relation to the new college

(*a*) Individuals having the necessary qualifications may join as members or associates
(*b*) An Irish faculty of the new college may be formed (the method of doing this is being investigated)
(*c*) An independent Irish college may be formed
(*d*) They may do nothing

The signatories of this letter feel that some definite step must be taken to ensure that Irish general practitioners may be enabled to secure full reciprocity with their opposite numbers in England and that nothing should be neglected which would tend to maintain the status of the general practitioner

It is scarcely necessary to point out that the field of medicine embraced by the term "general practice" has narrowed very considerably in recent years and that many G P s find themselves dealing only with the clinical trivialities while patients whom they could well treat gravitate elsewhere

In the opinion of most general practitioners there is room for great improvement in the training of medical students, for, while the great majority are destined to enter general practice, they are never taught however briefly by a general practitioner, and rarely if ever see the run of-the-mill cases which make up a G P's round and are first introduced to the G P the hard way—hard alike for the newly qualified doctor and his patients

There is no intention among the undersigned that any new group, college, or faculty formed shall be a competitor or rival of existing institutions, but rather that it shall be a co-equal partner with the object of improving the professional status of the general practitioner secondary only to the maintenance of high ethical and clinical standards in the profession as a whole.

We appeal most earnestly for a full attendance of our colleagues in University College, Dublin, on Sunday March 15, at 11 30 A M

DAILY PAPER PANTHEON

SIR,—I should like to congratulate you on "Daily Paper Pantheon" in your issue of Jan 31 As doctors we can count nothing human as alien and any clues to the discontents of our time must be specially welcome to us

If, as Dr McGlashan says, "the *gods*" are inevictable tenants of the human heart, how foolish have been the intelligentsia of the West in rejecting, and in persuading popular fashion to reject, that most profound and evocative version of the story of the paradoxical hero which is its religious heritage

My own conviction of the truth of Christianity does not derive from its correlation with the universal common denominator of the basic spiritual needs of mankind, but the fact is of great value for apologetics It is difficult to think too hardly of those persons who, in pursuit of a false simplicity and an allegedly higher concept, have tried to purge Christianity of its supernatural elements and have thereby done more to render it unattractive to the masses than all the atheists and unbelievers in frank opposition

JOSEPH V WALKER
Darlington

PARONYCHIA

SIR,—May I reply to some of the points raised by correspondents following the publication of my article (Jan 17)

I am sure that Dr Wheatley (Jan 24) is right when he suggests that usually paronychia can be—and is—aborted in general practice by the early exhibition of penicillin Sepsis of the hand can nearly always be aborted by the *early* exhibition of penicillin, because it is almost invariably due primarily to infection by sensitive organisms Such treatment must be very early in some cases, because in the subcuticular type of paronychia spread may be very *rapid*, and occasionally twenty four hours is long enough for a case to become out of reach of conservative measures Once pus forms the situation changes, and surgery is indicated—as it always has been Nowadays, however, operation on an abscess is incomplete if the only object is to "let pus out" Operation is also aimed at letting the antibiotic in, and this is a second principle which should activate the modern approach to minor surgery Failure to appreciate this is at the bottom of many so called "resistant" infections

The routine dosage of penicillin is that referred to by Ellis[1] We have not tested our organisms against chloramphenicol and penicillin mixed together, so I cannot comment on this, but I cannot endorse health personnel, resources and organisation, medical research, finance, special problems, and special population groups. The highlights are the recommendations for the establishment of a Department of Health and Security, and of a Federal Health Commission.

---

[1] *Brit med J* 1952, ii 1321

[1] Ellis, M *Lancet*, 1951, i, 1038

DEFINITIONS

The commission defines health as optimum physical, mental, and social efficiency and well-being; and it emphasises the responsibility of society to assure its citizens access to professional services, education concerning personal health practices, and a reasonably safe environment. "Future accomplishments, however, depend to an even greater degree upon the individual's assumption of responsibility for his own health."

The doctor is defined in the introductory comments as the leader of the over-all efforts, but as one member of a well-trained team composed of dentists, nurses, technicians, and many other professional workers.

DIFFERENCES AND PARALLELS

It is difficult in Britain, still hard-pressed as a result of two world wars, and in straitened economic circumstances, to appreciate the almost adolescent vigour of the American outlook on the future; and this report must be read with two basic facts in mind. First, the population of the United States has doubled in fifty years; and secondly, Americans are still always on the move. Some 4–5 million people move from one State to another in the course of a year, and another 4 or 5 million from one county to another within a given State. Each year over 3·5 million babies are born, and the population is expected to reach 193 million by 1975.

Allowing for differences in outlook it is interesting to see how history tends to repeat itself.

> "The high number of rejectees among young men called for military service in World Wars I and II and the present Korean episode have awakened the American people to the fact that despite superior medical service and low death rates, Americans are not enjoying as good health as might be expected in this country."

The commission recommends that the Federal government develop adequate methods to measure morbidity.

HEALTH WORKERS

The report underlines the need for more health workers. The minimum estimate of the physicians needed in 1960 is 22,000 more than the predicted supply, and the commissioners are "alarmed at the progressively severe financial situation of our medical education system." Dental research is an urgent need. Dentists are too few; and the more effective utilisation of dental hygienists and of dental assistants is thought to offer the greatest hope for making dental care quickly available to more people. When the report turns to nursing it sounds a note of anxiety, amounting almost to panic, even though there are now more than 365,000 active nurses, compared with 12,000 in 1900. The shortage in 1960 may exceed 50,000. It is not always easy to understand American nursing trends; for it sometimes seems that graduate nurses are turning away from the traditional concept of nursing and becoming administrators, teachers, and clinical assistants, while bedside nursing appears to be in danger of relegation to the less highly trained. Whether that is so or not, the commissioners believe that nursing should become a part of the general educational system of the nation.

The section dealing with paramedical workers—X-ray technicians, dietitians, physical, occupational, and speech therapists, social workers, hospital administrators, and others—is of particular interest.

> "While the several groups of paramedical workers require somewhat different training, there are also basic subjects in which several groups can be trained together. Some universities are already organising schools of 'Auxiliary Medical Services' for the joint recruitment and training of several paramedical groups. This type of program points the way to better training, better use of teaching staffs, and should go a long way in developing workers for the health team."

The report calls for removal of discriminating bars against the training of Negroes in the health professions. Dr. Hinsey expresses his doubts about the advisability of Federal aid in health education, as recommended in the report, with the possible exception of that in graduate schools of public health.

HOSPITALS

The report leaves no doubt as to the place of the hospital.

> "Hospitals are at the heart of our modern medical system . . . more and more it [the modern hospital] is becoming responsible for a continuing flow of health services to the community, supplying preventive services in health centers at one end of the line and rehabilitative and home care services at the other end."

The replacement of obsolete hospitals, and especially outpatient units, is urgently needed.

> "Today a good hospital is in reality a health center which places increasing stress on preventive and restorative services which keep the patient out of a bed. Home care and rehabilitation services should be developed in association with the hospital, which should have also auditoria for medical and community health organisations, and should possess a fine medical library. Every physician in the community should have some affiliation with a hospital."

ORGANISATION

> "The genius for organisation so characteristic of American life in general, is conspicuous in the health services by its absence. . . . In reality most of the American people grope their way through a haphazard array of health services without the guidance of a personal physician."

So begins the section on organisation of health services, and similar frankness is evident in the account of unethical practices which detract from the quality of medical care. Fee-snatching and fee-splitting are touched on, and also ghost surgery—i.e., deception of the patient as to the identity of the doctor who performs an operation.

Regionalisation of health services, and in particular joint use of laboratory, X-ray, and other facilities, is suggested, and also joint purchasing of supplies by a group of hospitals; and it is recommended that Federal loans be made to local organisations wishing to institute prepayment plans associated with group practice. Organised medical bodies are recommended to review their attitude toward group practice in a spirit of tolerance.

The comments on medical research are equally outspoken. "Last year's total expenditure of 180 million dollars amounted to only three tenths of one per cent. of the Nation's defense budget. It was less than the amount spent on monuments and tombstones." The Federal government itself spends over two hundred times as much on military research as on research into heart-disease. Many medical investigators are forced to jump from project to project without any secure underpinning. Research grants should be allocated to all agencies with promise in the health field, not just to medical institutions.

On the thorny question of financing personal health services the commission favours, with proper organisation, the prepayment principle; but it is significant that Walter Reuther, Albert Hayes, and the secretary of the National Consumers' League, dissent. They feel that the objectives set forth throughout the report should be accomplished through a National Health Insurance Act supported by joint employer-employee contributions and tax revenues. Clarence Poe agrees with the

The other was in an old lady who had had a ureteric transplantation and a hysterectomy, she had only one kidney, which was subsequently found to be riddled with chronic nephritis, so the fatal hæmorrhage which ensued was not surprising This emphasises the need to include full clinical details on the request form

Dr Bjerkelund pleads for "long continued treatment of ambulant outpatients" Surely the danger of recurring thrombo-embolic incidents could be substantially reduced if the patient were maintained on ethyl biscoumacetate for longer than is now customary We cheerfully subject people to lifelong liver and insulin injections with accompanying laboratory control, and yet we are reluctant to do the same in the case of dicoumarol or its derivatives If a dosage advisory service could be arranged on the lines indicated above, most of the principal objections to the use of this drug would be overruled Is it not worth it ?

HALLUX VALGUS

SIR,—Your leader last week stimulates me to make certain observations on this important subject

Apart from terminal-phalanx hallux valgus, which is congenital, hallux valgus is, I understand, found among peoples who have always been barefoot only in adults, and the disorder appears to be due to injury of the first metatarsus or proximal phalanx Developmental hallux valgus is, I believe, virtually unknown among children who have always been barefoot

Since in this country some 50–75% of adolescents have a developmental hallux valgus (as any school medical officer will testify) only some all-embracing factor, such as tight shoes, can be involved Again, since our Ealing shoe scheme showed quite clearly among growing children that the supply of well-fitting shoes leads to the disappearance of hallux valgus, it is difficult to accept your assumption that "there is commonly no apparent cause whatever for hallux valgus"

The child with a broad foot needs no wide metatarsal angle to have difficulty in finding suitable fittings in foot wear, and children's shoes at a price within the reach of the ordinary parent are made in only one fitting At least half the children could not therefore possibly obtain satisfactory shoe fittings even if there were enough trained shoe-fitters in the shops and every parent were aware of the importance of securing correct fittings Every child needs a new fitting approximately every three months, but with shoes at their present cost it is almost impossible for parents to follow this practice

How sad it is that this preventable condition is not prevented !

CONGENITAL DEFECTS FROM MATERNAL RUBELLA

SIR,—Mr Ian Robin[1] recommended that, in order to avoid danger of infection with rubella during pregnancy, every opportunity should be taken to infect girls with the disease before leaving school I am in absolute agreement, and there seems every advantage in following such a course in a school where all the girls are boarders But, as medical officer to a girls' public school in which only 153 of the 521 girls are boarders, I find the decision by no means so simple Some of the girls may be returning daily to a mother who may herself be pregnant, or they may share public transport and entertainment with pregnant women, the risk would therefore be spread over a large section of the community I should welcome the views of others who may be faced with the same problem

EXAMINATION OF RIB BONE-MARROW FOR TUBERCLE BACILLI

SIR,—The discrepancy between our findings and those of Dr Marsh and Mr Barton,[1] who found no tubercle bacilli in the rib bone-marrow of their patients, may be explained by the following facts

(1) The hæmatogenous (disseminated) form of tuberculosis is commoner in children

(2) The sternum is relatively richer in marrow than the ribs

In our work on this subject we have made comparative studies of blood, bone-marrow, and gastric-juice cultures from tuberculous children, and these have confirmed our previous results This study encouraged us to make a more detailed review of the literature, and we have found that the bone-marrow of tuberculous patients has repeatedly given positive results in the past[2–5]

THE LATE Dr H W DIAMOND

Dr J B Wrathall Rowe writes "Dr Hugh Welch Diamond, who died at Twickenham in 1886, was a pioneer in the field of medical photography and photomicrography I should be grateful if any one with knowledge or early examples of Dr Diamond's work would write to me c/o the Medical Department, Kodak Ltd, Harrow, Middlesex I should also welcome information about Dr Diamond's descendants Dr Warren Hastings Diamond may have been his son, and he is thought to have had a grandson named R Hugh Clarke"

Medicine and the Law

Nationalised Hospitals and Negligence

THE degree (if any) to which the nationalised hospital and their staffs are protected from claims for negligence is still being worked out at the expense of plaintiffs and defendants In Bullard *v* Croydon Hospital Group Management Committee and Latta[6] it was alleged that a patient suffering from acute appendicitis was not operated upon till five days after admission to hospital, by that time, it was said, peritonitis had developed and death occurred on the day of the operation A claim for damages was brought against the hospital managers and the surgeon concerned The hospital managers replied that, in so far as they were responsible for the treatment of the deceased, they undertook it as their duty under the National Health Service Act, the surgeon, they contended, was acting on their behalf or as an officer under their direction in the discharge of their responsibility, and they claimed protection from liability by virtue of section 72 of the Act

Section 72 provides that section 265 of the Public Health Act, 1875, shall have effect as if the public authorities referred to therein (local authorities, joint boards, and port sanitary authorities) included a hospital management committee Section 265 provides that nothing done by such authorities or any of their officers or other persons acting under their directions, "if the thing were done bona fide for the purpose of executing" [the Act of 1875], shall "subject them personally to any action, liability, claim or demand whatsoever"

Mr Justice Parker decided in favour of the plaintiff, the administrator of the deceased patient's estate He referred to section 13 of the 1946 Act which states that hospital management committees, notwithstanding that

Mr. BLENKINSOP asked the Minister what financial saving he estimated would result from the charges imposed under the Health Service Act, 1952; how much of this saving resulted from a fall in use of the services concerned; and how the savings compared with the estimates originally given.—Mr. MACLEOD replied: The estimated amount of the charges paid, or to be paid, in 1952–53 by patients in England and Wales under the 1952 Health Service Act is about £2 million. In addition, while figures to enable a complete estimate to be made are not available, the reduction in the demand for dental treatment and for hospital appliances for which charges are made compared with the previous year is estimated to show a saving of about £1¾ million. Comparisons cannot usefully be made with estimates framed in the expectation that the charges would operate for a full year and before modifications in the original proposals were made.

Bone-conduction Hearing-aids

In answer to a question Mr. MACLEOD said that a first consignment of bone-conduction hearing-aids had already been sent to the hospitals which distribute aids.

Flour-improvers

Mr. D. W. WADE asked the Minister of Food what progress had been made in the investigations into the existing methods of treatment of flour; and whether he would give an assurance that the process of agenisation would be abandoned.—Major GWILYM LLOYD GEORGE replied: These complex and important investigations into possible alternatives to agene as a flour-improver are requiring considerably more time than was originally thought necessary. They are being pursued with all possible speed, but it would be premature to take any action until they are completed. One or two possible alternatives have been presented, but it is obvious that very careful research must be undertaken before either can be accepted.

Health Service Resignations in Scotland

Sir THOMAS MOORE asked the Secretary of State for Scotland whether he was aware of the public concern in Ayrshire in regard to the efficiency of the National Health Service, with particular reference to the shortage of trained medical and surgical consultants.—Mr. JAMES STUART replied: If the hon. member will let me have particulars of any deficiencies brought to his notice, I shall be glad to consider them.

Sir THOMAS MOORE: While welcoming the Minister's suggestion, is he aware that there has been a disturbing number of resignations lately, especially amongst consultants; and is he satisfied that the West of Scotland Regional Board is adequately and effectively dealing with this unsatisfactory situation? Mr. STUART: I am assured that the regional board are taking proper steps to replace those who have resigned.

Mr. A. C. MANUEL: Is the Secretary of State aware that in the West of Scotland, and in Ayrshire in particular, since the inauguration of the National Health Service we have had a better full-time consultant service than ever previously existed; and that the doctors generally have expressed to me their satisfaction at the better service now available?

In England Now

A Running Commentary by Peripatetic Correspondents

LEISURE, like the conversation that goes with it, is dying; and we are hastening its end. In our fathers' day a whole section of society was dedicated to its pursuit; and none thought a whit the worse of a man for belonging to the leisured classes. But today the very word leisure bears a sting of reproach. Braving public opinion, the Chelsea Clinical Society last week met to hear from three distinguished speakers—a writer, a surgeon and a broadcaster—how we might win our way back to the Pursuit of Leisure. Mr. John Betjeman would have none of this. By speaking for only three minutes he slyly implied that he was making way for others better qualified to talk, and his brief words were largely directed to showing that no stigma of leisure could be applied to him; if, he declared, he liked what he did he wouldn't want any leisure. Leisure was an invention: and here presumably he meant that like other inventions—the safety-pin, the steam engine, and even television—it could be eradicated if only we turned our minds to the task. A similar personal disclaimer came from Mr. Gilbert Harding—the Mr. Harding who in other fields has spoken bravely. Only Sir Heneage Ogilvie stood his ground; but it was carefully chosen medical ground on which he spoke well of leisure as a counterpoise to work. The lesson seems to be that this word is now taboo except in the consulting-room: and we should thank the members of the Chelsea Clinical Society for setting aside some of their less hurried hours to establish this.

* * *

The study of man's reaction to changing environment is now a popular pastime. I have been making an unofficial pilot study of my reaction as a householder to the august body which now runs the local hospital.

The bureaucratic mills grind slowly, but with an air of majestic purpose. The first victims were some moderate-sized houses in which the ci-devant bourgeoisie once raised happy families. These were smartly converted into staff quarters and maternity units, so that our rather ordinary neighbourhood has now a busy professional air. Starched white caps and scarlet-lined cloaks charm the eye in the daytime and ambulance noises make my nights hideous. After a suitable interval a nursing-home was drawn into the net. This raised a generous amount of heat, even assuming atomic proportions, but the deed was not undone and the opposing forces have withdrawn to regroup.

But now a bureaucratic shaft has found a target right in the middle of our domestic hearth. Our invaluable daily help has decided to throw off the shackles of private enterprise and give her services exclusively to the hospital. It would take the genius of Milton to describe the despair with which we contemplate the future of our fast dwindling paradise, and my pilot study has turned a bit introspective. . . .

* * *

During the recent gales our sanatorium was soon cut off from electricity and water. On the first morning of the storm we were approached by a delegation from the patients' club, who, apparently unconcerned about their own welfare, wanted to know what was to happen to their tropical fish. We answered, civilly enough, that we were rather busy just then, and quickly retreated to our quarters to consult our small medical reference library. The fish, some three dozen of assorted species with their young, lived in a tank in a remoter part of the sanatorium property: and the fixity of their internal medium was controlled by a device of science, worked by electricity. The problem was of keeping the temperature of the tank above 75° Fahrenheit under the prevailing chilly conditions. Coal fires in the hospital numbered two, and the tank could not be moved.

On going through our literature, we found we had mislaid Dr. Bernard's paper; other oracles we had consulted in the past could give us no guidance. Our eyes fell on our stone hot-water jar which lay on the floor, where it had been blown out of the hands of a maid-servant earlier that morning. By applying the late Mr. Archimedes's principle, two hot-water jars were

Obituary

HOLBURT JACOB WARING

Bt., C B E , M S , B Sc Lond , D C L Durh , LL D Brist ,
M S Cairo, F R C S , F R A C S

Sir Holburt Waring, whose death we announced last week, made important contributions to medical education On the ward round and in the operating-theatre he was a stimulating teacher, in the hospital board room he was a generous and forceful advocate of expansion, and in the counsels of the Royal College of Surgeons, the University of London, and the General Medical Council he initiated reforms in the medical curriculum

Born in 1866, the son of Isaac Waring of Southport he was educated at Owens College, Manchester and at St Bartholomew s Hospital, from which he graduated M B with honours in 1890 In the following year he took the F R C S and in 1893 he obtained the M S and the gold medal for surgery Meanwhile in a succession of house-appointments at Barts he had quickly won recognition, and appointment to the staff and to the lectureship in operative surgery followed in due course

[Elliott & Fry

On the outbreak of war in 1914 as a Territorial he was at once called up, and with the rank of lieut-colonel he was given charge of the surgical division of the 1st London General Hospital (T F) He was mentioned in despatches, and was appointed C B E in 1919

His association with the administration of the University of London began in 1911 when he was elected to the senate, and in 1920 he became dean of the faculty of medicine, and in 1922 vice-chancellor of the university He had been appointed to the court of examiners of the Royal College of Surgeons in 1911 and to the council in 1913, and from 1932 to 1935 he was president of the college From 1917 to 1932 he represented the college on the General Medical Council, which he served as treasurer and he held the same office for the Dental Board from 1921 to 1932

Much of his work in his own specialty had dealt with the surgery of malignant disease, and the Imperial Cancer Research Fund was another academic body which appointed him its treasurer When he retired from his office last year he was elected a vice-president of the Fund

With the years accrued the honours he had earned In 1925 he was created a knight, and ten years later a baronet *The Royal College of Surgeons of Australasia* had elected him to their honorary fellowship, and he had received honorary degrees from the Universities of Durham, Bristol, and Cairo His varied work and interests had touched life at many points, and his achievements are best described in tributes from friends *of different ages and different specialties*

F R F points out that though the close connection of the London medical schools with the university is now accepted as obvious and natural, it was far from being generally accepted between the wars, and Waring worked unceasingly to bring it about

" As a first step he succeeded in obtaining a charter for St Bartholomew's Hospital Medical College, so making it administratively independent of its parent hospital, but he had to use all his influence to effect at that time what has now under the National Health Service become a required condition for all the medical schools in London It was a source of wonder to his friends and colleagues how he managed to reconcile his loyalties to the different bodies in which he held office, but he accomplished this successfully and worked continuously to promote coöperation among the many institutions concerned with medical practice and medical education in London Only those who were involved with him in obtaining the new ward block for St Bartholomew's Hospital know how hard he worked in planning it down to the smallest detail, and how carefully he studied the designs of hospitals in this country and abroad before reaching conclusion. [illegible] his colleagues, both medical and non medical, shared with him the responsibility for final decisions his was the dominant voice on all occasions Doubtless this dominance was exercised in his other activities and accounts for much of the respect, tinged with fear, that he inspired in his students and in many of his contemporaries He will not be remembered [illegible] great surgeon or a great teacher, but his methods were successful in forcing essential knowledge into the heads of many students who had difficulty in learning for themselves and many a story of his explosive language will be told for years to come His death removes a colourful personality who gave all he had to the welfare of medicine and medical education, and in so doing effected much of lasting val[illegible] He will be remembered also by those who knew him best f[illegible] his courtesy and kindnesses "

Of Sir Holburt's many excellent attributes the one that stands out most vividly in H. W 's memory, and dwarf[illegible] everything else, was his intense interest in his own hospital

" Where its welfare was concerned, it always came first and nothing else mattered Not always completely tactful in the way h[illegible] addressed his views, his persistence and thrust always sufficed to win the day and get what he wanted and thought right St Bartholomew's are very grateful for all the great improvements and advantages he secured for them Sir Holburt was a good judge of men and he possessed the valuable trait of being able to depute work successfully to others He had a beautiful pair of hands, and in his younger days he was a very neat and efficient operator When he retired, his invaluable help and the standard of service and behaviour he enforced on other people, and carried out himself in the hospital, was greatly missed, and always will be '

J E remains grateful for having had his basic surgical training from Sir Holburt

' An exact thinker himself, he insisted on his students carrying out examinations, writing notes, and expressing themselves in a similarly exact manner Brusque almost to the point of rudeness the Old Man, as he was affectionately called by all who worked with him, never forgot one of his old students, and many of them have reason to thank him for that personal letter of recommendation which can mean so much in a young man's career "

W R T admits that to all his dressers and to many of his house-surgeons Sir Holburt was an enigma, but suggests that there is no doubt that his brusque manner was something of a pose and partly accounted for by the rough handling he himself received as a young man from Harrison Cripps and others

" Sir Holburt was one of the last of the surgeons who may be said to have lived through the heyday of consulting practice the first quarter of this century , on one occasion going even as far as Nepal to operate He lived and moved in the grand manner, and to see the half hunter flicked open at just the right moment when examining a private patient was a revelation as to how this should be done As a judge of wine and cigars he had few equals, and he was most intolerant of dressers satisfied with beer from the White Hart and 'Gold flakes ' (then selling at less than a shilling for twenty) 'You young men of the present day who stand about with your hands in your pockets smoking cigarettes ' Great was the jubilation throughout the firm when someone spotted the Old Man buying a packet for himself one evening on Liverpool Street Station

' Until recent years he had substantial colliery interests and these helped to make him a shrewd man of affairs, with resulting benefits to any institution with which he was connected Although he liked to get his own way, he usually had sound reasons for wanting to do so

' His teaching was plain straightforward practical stuff and he expected his dressers under supervision, and most certainly, his residents to be able to tackle any ordinary task a attention is paid to the story and close observation made of the ways in which children react to pain, intussusception is one of the most clearly defined conditions in childhood. Certainly textbooks often give a misleading mixture of symptoms drawn from different stages of the disease; but on the first day—the period when it must be suspected for optimum results—the clinical picture is plain and the fringe of atypical cases is small. The onset is sudden; vomiting occurs in 9 out of 10 children; and blood is passed spontaneously by about half the children on that first day. Pain is always present, though we admit that sometimes it requires considerable experience to recognise it, as it will be expressed by different children in different ways. In many the traditional screaming occurs with each bout of colic: in others it is reflected in crying more often than usual: others again are exceptionally restless with whining and whimpering; while very rarely the child may simply blanch with the spasms without uttering a sound.

With proper sedation an experienced observer will feel the tumour in almost every case, except when the invagination is still confined to the small bowel; and although it is true that it is easier to feel the tumour when the bowel is in spasm, we do not agree that the tumour disappears when the bowel is relaxed. As regards surgical technique, a right paramedian incision is, in our opinion, superior to an incision in the right iliac fossa; and experience has shown that in the younger children there is no need to remove the appendix. We can certainly see no reason for the use of a combined technique of enema reduction plus laparotomy as used by Collier.

We would stress again the constancy of the clinical picture of this disease, apart from feeling the abdominal tumour, because it is upon this that we must rely if the family doctor is to suspect it with increasing frequency within the first twenty-four hours. What is more, this very constancy makes diagnostic radiography unnecessary and time-wasting except in the few subacute or chronic examples of the disease.

We hope to present our material, and with it the difficulties of this subject, more fully at a later date; but we felt that your article called for an immediate reply.

REGISTRATION OF FEVER NURSES

SIR,—Dr. Grant's letter last week draws attention to a matter which is causing great anxiety to those concerned with the staffing of fever hospitals.

The General Nursing Council maintains that it is concerned solely with the training of nurses and not with the staffing of hospitals, but surely it can be argued that the training of nurses should be related to the nursing services required by the public.

There has been a large drop of infectious diseases over the last ten to fifteen years, but the work carried out in a modern fever hospital is still a very essential part of the health service. Much of the work consists in the treatment of acutely ill babies, and this requires possibly greater nursing skill than any other form of treatment. In a large city there is always the risk of serious epidemic disease—only a few years ago we had to treat over a hundred cases of paratyphoid fever in this hospital. The danger of poliomyelitis is an urgent one, and the recent outbreak in Copenhagen makes one view with concern any move which would lead to a precarious state of staffing in our infectious-disease hospitals. Even diphtheria is not completely absent; in the last two months we have treated ten clinical cases, including one fatal case. A too-ready belief that infectious diseases are now of little account from the nursing point of view may lead us into danger.

It must be admitted that many fever hospitals are too small to offer suitable training for nurses, but this is no reason for abolishing the two-year training course in infectious diseases in the larger hospitals where student nurses can gain a wide variety of excellent experience.

If the Fever Register is abolished the infectious-disease hospitals will face grave difficulties.

A. B. CHRISTIE
E. A. BURNS.

Fazakerley Hospital,
Liverpool.

AUGMENTED RESPIRATION

SIR,—I wish, without intending to depreciate the work of Mr. Donald and Miss Lord, to comment on a statement in their letter last week which has a wider relevance.

They claim that the negative pressures used in their respirator encourage the return of blood to the heart, and I think they mean to contrast the effect of inflating the lungs by pressure applied through the air-passages. This notion is widely held, but it is mistaken. The negative pressure exerted by a Drinker-type respirator does not enhance cardiac filling, because it is applied to the limbs and abdomen as well as to the thorax. In fact, the distribution of pressure gradients (and hence the circulatory effects) is identical with that produced by applying a similar, but positive, pressure through the air-passages. We have in this department recorded the blood-pressure during artificial respiration and have confirmed that lung inflation, whether by negative external or positive internal pressure, drops the stroke volume, whereas, of course, normal inspiration increases it.

The practical inference is that, the circulatory and other physical effects of the two modes of artificial respiration being the same, the choice between them may be made on grounds of convenience.

School, London, S.E.1.

CHILD-WELFARE CLINICS

SIR,—When considering the future of the child-welfare clinics a few facts must be borne in mind. They are:

1. The most suitable person to do this work is undoubtedly the family doctor.
2. There is no official barrier whatever to prevent him from doing this work now; for in most areas some interested doctors have their own clinics, and some of course have national reputations in this field.
3. Local authorities do this work for the undeniable reason that in the past general practitioners have neglected to do it.

It is quite impossible for the local authority to staff and equip an infant-welfare centre for every family doctor; for instance, in Ilford there are fifteen centres and about seventy general practitioners. It would be equally inappropriate to select fifteen of these seventy and ask them to look after children on the lists of other doctors.

A large number of practitioners cannot or do not wish to do this work because they are not interested or their premises are unsuitable.[1] We have all seen queues in the rain outside their surgeries in industrial towns and know how crowded the waiting-rooms must be and how they may often be filled with unsuitable fellow-patients, such as open cases of tuberculosis.

Accordingly, until such time as most family doctors are interested in health education and have suitable premises for this work (such as may be provided in health centres) the local authority must continue to provide this service. When these conditions are fulfilled, local-authority infant-welfare centres will disappear for the simple reason that they will not be wanted.

Should they be precipitately discontinued there is no doubt that the vast majority of children—say, applied his talents with great patience to each new problem, showed an impartiality which won him the regard of police and the law, and *never failed to give sound advice of a conservative kind* He appeared in many famous trials and he survived a public esteem with the same charming 'grand old man' detachment as he surveyed the Bench and Bar Many will miss this warm hearted man and will regret that he was denied the pleasures of relaxation in *retirement* He would not have lacked visitors and invitations, intellectual and more rustic diversions, conversation, and a ripe enjoyment of later years His life had been full, he had enjoyed it enormously, and it needed only a chapter of happy retirement to complete it"

---

[1] See Collings, J. S. *Lancet*, 1950, i, 555.

Dr Grace is survived by his wife and two sons, one of whom took his M B at Liverpool in 1950 and is now serving in the Navy His brother, Dr A W Grace, is professor of clinical dermatology at Long Island University, New York

GORDON CAMPBELL KINLOCH REID

M B St And, L D S

Dr Reid, pathologist of the Walsall group of hospitals, died at his home in Walsall on Feb 6, at the age of 49

He was born at Elgin, but he spent his boyhood at Perth, where he attended the Perth Academy From there he proceeded to St Andrews University In 1929 he took the L D S and graduated M B He held a number of hospital posts and spent some time in general practice before he became resident surgical officer to New Cross Hospital, Wolverhampton, in 1935 Through the laboratory service of the hospital he was brought into contact with the practice of clinical pathology, which made an immediate appeal to him, and in 1938 he joined the staff of The Royal Hospital, Wolverhampton, in the joint capacity of resident medical officer and assistant pathologist

Dr Reid devoted immense energy to the development of the Wolverhampton and district blood-transfusion service, then based upon the pathological department of The Royal Hospital It was largely owing to his efforts in its early days that this service was able to bear all calls upon it at the beginning of the late war before it was merged into the Emergency Blood Transfusion Service In 1940 he joined the R A M C, and as a specialist in pathology with the rank of major served with distinction in the Eighth Army both in North Africa and on the Continent Under the pseudonym of "Pixie" he was widely known throughout the medical service of the Eighth Army After D-day he was mentioned in despatches for conspicuous gallantry and devotion to duty

After demobilisation, for a short time he again served in the pathological department of The Royal Hospital, Wolverhampton. In 1946 he became attached to the Walsall General Hospital, first as assistant and later as full pathologist, and under the National Health Service he became consultant pathologist to the Walsall hospital group In this post he unstintingly applied his immense energy, and in a short time had brought the pathological service centring upon these two hospitals to a high state of efficiency Since 1951 his work had been interrupted by his serious and disabling illness, but with great fortitude he returned to his post in the spring of 1952 and continued to fulfil its duties until December

S C D writes "Dr Reid was a great clinical pathologist, exactly of that type of which the national hospital service stands most in need He read widely and kept himself well abreast of current knowledge in all branches of his subject But the secret of his success as a clinical pathologist, and the reason for the universal regard and affection which he came to command, was that to him the welfare of the patient, whether in or out of hospital, was a major concern His years of *clinical experience*, both in general practice and in hospital posts, stood him in admirable stead in bringing the work of the laboratory and of the wards into intimate and fruitful contact His laboratory was freely open to all general practitioners of his neighbourhood, and in it both they and their patients were always sure of a ready welcome and a sympathetic and kindly hearing"

Dr Reid married Miss Dorothy Pollitt, S R N, in 1946, she survives him with two children

RANSOM PICKARD

C B, C M G, M D, M S Lond, F R C S, D P H

Colonel Ransom Pickard, who died on Feb 9, at the age of 85, was well known in the West Country as an ophthalmologist, and he was also one of Exeter's most distinguished citizens

He graduated M B with first-class honours from St Bartholomew's Hospital in 1889, and after holding house-appointments there and at Moorfields he took higher qualifications in his specialty before he settled down in Exeter in the '90s After a few years in general practice he was appointed surgeon to the West of England Eye Infirmary No man ever took his hospital duties more seriously, or took more trouble over his patients, and as a hard worker himself he expected a high standard from others It was not surprising that he soon built up a large private practice, and such was his reputation that he retained an unusually large measure of it after his retirement from his hospital post in 1932

In the 1914–18 war Pickard was mobilised as lieut colonel in command of the 1st Wessex Field Ambulance, which he had been instrumental in raising, and he saw immediate service in France He was later promoted A D M S of the 48th Division with the rank of colonel and he served in North Italy with this division until demobilisation Five times mentioned in despatches, he was awarded the Italian croce della guerra and was appointed C B and C M G

Pickard contributed fairly often to the medical journals, and he was particularly interested in glaucoma and in cases of low tension with disc cup enlargements He took immense pains over the papers which he wrote, and he would often turn up at the Eye Infirmary at 8 A M to take a tonometer reading He was also regular in his attendance at medical meetings and he seldom failed to contribute to the discussion something that was worth hearing He never talked nonsense and he never failed to command the respect of his colleague Perhaps it was for that reason that he was chosen for the unenviable position of chairman of the local committee which in the 1939–45 war had to decide which doctors should serve in the Forces and which *should* remain behind

But Pickard was a citizen as well as a doctor and for several years, until 1947, he achieved the *distinction* unique for a former member of the surgical staff, of being president of the West of England Eye Infirmary He had already served Exeter as sheriff (*1906–07*), and as mayor (1927–28), and he had a long association with the University College of the South-West, *of* which he became a vice-president He was also a vice president of the Exeter Drama League, and a past president of the Devonshire Association and of *the* Devon Archæological Exploration Society

M D B writes "One of Pickard's chief *delights* was walking Almost every Saturday of his life, dressed for the part, he went for a long walk in the country He really *loved these walks (and the planning of them)* and the Devon country they were a part of his life, and nothing—least of all bad weather—deterred him from taking them He never had a car, he always walked everywhere, and he never seemed to feel the cold I can only remember seeing him *in an* overcoat once or twice—a rather inadequate garment disliked and despised by its owner, who thought almost as poorly of a mackintosh In earlier years he was a keen mountaineer, and a member both of the Alpine Club and of the Swiss Alpine Club

"Pickard did not marry till he was 45, but he had forty years of *extremely happy married* life Mrs Pickard shared many of his interests and was *the* ideal wife for a personality which in his younger days was perhaps a little rugged and which she succeeded in mellowing into the fine old man that Exonians remember so well

"He had always been a non smoker and a teetotaller, and last but not least, *he was a life long Methodist* Every Sunday, Dr. Wheatley's suggestion that penicillin and streptomycin should be applied locally. Topical streptomycin s particularly liable to produce skin reactions, and opical penicillin is not free from the same disadvantage. I have not yet seen a skin reaction with chloramphenicol. 5% chloramphenicol in propylene glycol is not expensive; 100–150 applications cost 8s., if the solution is made up in one's own dispensary. The total cost in antibiotics of treating a case of paronychia was 3s. 7d.; it is now less.

Mr. Jones's investigation of seasonal variations (Jan. 31) interested me greatly. I agree there are so many factors that it is difficult to prove anything. I have, however, taken from last year's records on septic hands (976 cases) a few figures which may be relevant.

In the months January, February, March, October, November, and December, 58 cases of common septic hand conditions took over a fortnight to heal, 21 over three weeks, and 10 over a month. In the months April–September the corresponding figures were 26, 10, and 4. The figures for paronychia were: over a fortnight, in the winter 18 and in the summer 4; over three weeks, in the winter 4 and in the summer nil; over a month, in the winter 2 and in the summer nil.

It is the *clinically* resistant cases that we hope to abolish. Some, as I have shown, are due to bacteriological resistance, and chloramphenicol will help. Many are due to faulty surgery in the first place, and bacteriological resistance is acquired secondarily. Paronychia is the first septic condition of the hand in which penicillin-resistant organisms have been noted in significant numbers on first attendance at the clinic.

This casualty appointment, like many others, has been unfilled for some time: and in the past year no less than seventeen housemen have been detailed, at one time or another, to operate on the cases. Under such conditions it is impossible to maintain a consistently high standard. Nevertheless the 230 cases of paronychia treated since the principles I adopted have been emphasised, have had an average duration of treatment of 7·1 days. This is nearly a 40% improvement on anything we have had before, and exactly half the average disability in 1950.

Royal Infirmary,
Sunderland.

T. G. Lowden.

A SURGICAL POLICY FOR PEPTIC ULCER

Sir,—May I congratulate Mr. Orr and Mr. Daintree Johnson on their excellent article in your issue of Feb. 7? They have recognised the surgeon's dilemma: excellent as ulcer surgery is, a fairly high resection is necessary for sure relief, and the higher one goes the more likely one is to encounter untoward effects (of which we have seen examples from all over the country). The authors' plan of operation is designed to secure the benefits of gastric surgery without its disadvantages.

In my own clinic we treated a small series of patients by limited gastrectomy with vagotomy, and we were well pleased with the results, but we are waiting a little longer before going on. Meanwhile, we are giving an extended trial to another promising procedure, the results of which have not yet been assessed for publication. These latest figures from Mr. Orr and Mr. Johnson are a strong encouragement to us to begin a second series of limited gastrectomy with vagotomy in suitable cases.

It is only from the most careful personal analysis of an adequate series of cases such as this, that any important deductions can be drawn. The authors mention that they have also had access to a second series, operated upon by a colleague. I should like to emphasise the value of this method in which the same observer takes stock of both series and can therefore safely draw comparisons. We also have made a start in this direction, and we hope soon to extend similar inquiries much more widely.

Finally, may I voice one criticism? I believe they are wrong in supposing that even the most cunning questionnaire is as good as an interview: for example, the signs of riboflavine deficiency have to be looked for if they are not to be missed. Moreover, patients who have, through surgery, been relieved of their life-long ulcer pains are often reluctant, unless pressed, to admit to even so gross a feature as bilious vomiting, and, moreover, they often mistake bile for food. In this article, the incidence of bilious vomiting is about "right," but that of the vomiting of food seems to me too high.

Department of Surgery,
University of Liverpool.

Charles Wells.

METHOD OF ADMINISTERING DICOUMAROL

Sir,—The paper by Dr. Bjerkelund (Feb. 7) was very interesting to us here as, for some years, the determination of prothrombin levels and the task of working out further dosages of dicoumarol or of ethyl biscoumacetate ('Tromexan') has been entrusted to the biochemist. This arose because the requests were often inscribed "please advise dosage of anticoagulant," and also because we found commonly that inexperienced housemen either were reluctant to order enough dicoumarol or ordered excessive amounts. Furthermore, daily prothrombin estimations were becoming a burden to both staff and patients. Consequently the following scheme was devised:

The initial request form contains full clinical details, including any dosage already given. The prothrombin is determined by Quick's one-stage method using rabbit-brain thromboplastin, and the result is reported as the index and corresponding percentage normal. This is written direct on to the request form together with dosage details for the evening of the day of test, the following day or days, and the morning of the next test day. The form then goes back to the ward; or in the case of outside hospitals in the group the report is telephoned. Usually tests are done every other day—chiefly Mondays, Wednesdays, and Fridays.

The advantages are briefly:

1. The report gets to the ward quickly and treatment can be started with little delay.

2. There is no laboratory office work except to note incoming requests in the day-book; there is no typing (to save technical time, the report is written within a rubber-stamp framework), and we keep our own record of the dosages in the laboratory prothrombin-time book.

3. Tests are necessary only every other day.

4. In the case of ethyl biscoumacetate, the dosages are divided into morning and evening tablets, and usually one 300 mg. tablet is given at 6 A.M. on the day of test to maintain a satisfactory level until the result of the test is known.

5. Whilst it might be argued that it is unwise to leave the dosage to the laboratory, in practice this works very well; for the biochemist, unlike the houseman who has many such drug dosages to work out, can bring a fresh mind to the problem. Furthermore, it is obviously an asset to have someone who has been concentrating on this dosage problem for several years and who has the patient's previous figures at his finger-tips. Indeed, provided full clinical details are given, it is possible for the laboratory to point out the inadvisability of starting a course of ethyl biscoumacetate in, for example, pregnancy, if this has been overlooked by the clinicians.

6. General practitioners are more ready to treat their own patients instead of admitting them to hospital. In the case of ambulant patients the blood is taken by the laboratory, the result and dosage telephoned to the doctor, and the dosage alone telephoned to the patient. The doctor then has merely to check the clinical side every other day. He knows what dosage the patient has been instructed to take, and can alter it if he considers this necessary. This is surely a good example of a general practitioner receiving immediate and full coöperation from a hospital department and yet maintaining full control of the patient.

7. Only two cases of major hæmorrhage in the past four years can be recollected. One was in the early days, through too infrequent testing, and was controlled by transfusion.

University of Liverpool

The following have been successful in the examination for the diploma in tropical medicine and hygiene

K M Aboud A N Basu, S N Bhattacharya K R I Hariharan, *R Hecker E S Jones, G Moles, Y Na Songkhla, H C C Nwankwo, T Viriyakul

hey may be exercising functions on behalf of the regional hospital board, "shall . . . be liable in respect of any liabilities incurred (including liabilities in tort) in the exercise of those functions." He was not to be convinced that, when section 13 plainly said that hospital managers could be liable, section 72 would prevent them from being sued. He had been pressed with a Scottish case (*Davis v. Glasgow Victoria Hospitals*) in which it was decided in 1950, on the corresponding but not identical enactments relating to Scotland, that the hospital management could not be sued. The Scottish case, he said, was not binding upon him. On the preliminary point of law, therefore, the plaintiff has succeeded; but leave to appeal has been granted. It is not a matter which should be left in doubt.

Public Health

Mortality in the North of England

THE Registrar-General's Statistical Review of the year 1950[1] drew attention to the high mortality-rate in the north of England as compared with the south. Dr. C. Metcalfe Brown, medical officer of health for Manchester, has now put before the city's health committee an analysis of the mortality figures in the Manchester area, in which he has compared them with those from other parts of the country and drawn some conclusions about the causes of the difference between north and south. He has used as illustrative figures the adjusted mortality ratio and the infant-mortality rate, which, provided areas of large enough population are considered, generally agrees with the mortality ratio when different areas are being compared.

The report sets out some examples which show that, as judged by mortality-rates, the healthier parts of the country are in the south and the least healthy in the north-east. Details are then given for those districts of Lancashire and Cheshire which adjoin Manchester, Salford, and Stockport. The parts to the south show up best—most of the county districts of Cheshire have a lower adjusted mortality-rate than that of England and Wales as a whole. But most of the county boroughs to the north have a mortality ratio close to the Manchester figure of 1·22. Along the railway line which approaches Manchester from the south-west, through Hale, Altrincham, Sale, and Stretford, the mortality ratio and the infant-mortality rate show a steady turn for the worse, the infant rate rising from 8 per 1000 live births at Hale to 37 in Manchester. Atmospheric pollution increases considerably along the same railway line, factories and workshops become more numerous, the houses crowd more closely together, and living conditions deteriorate.

Dr. Metcalfe Brown sums up the disadvantages of the north as follows:

(1) Lower temperatures.
(2) Less sunshine and daylight.
(3) Greater atmospheric pollution.
(4) Greater congestion of houses.
(5) More defective houses.
(6) More intense industrial development.
(7) Heavier industrial occupations.

He lays the chief blame for the higher mortality-rate in the north on poor housing, industrialisation, and smoke pollution; and to these he adds the high proportion of unskilled workers in the population.

"Industry needs the highly skilled craftsmen but it also needs and attracts the unskilled workers. Many of these labourers are people of high intelligence but some are not. They have not acquired the skill and greater prosperity of the craftsmen because of one or more factors such as lack of opportunity, ill-fortune, lack of ambition which is not necessarily reprehensible or physical or mental incapacity. They are not, with notable and frequent exceptions, so enlightened or educated as a skilled worker in many matters, and one of the most important of these is healthy living. They and their families tend to occupy the worst houses of the town because they are cheaper and they have learned, and in many cases have been compelled, to put up with bad conditions. Perhaps they may have never had the opportunity of knowing any other. Their wage level is the lowest in the community and that, together with the other points as well as their poor environment, has resulted in a standard of life lower than that of the rest of the community. And there they will stay unless they are helped."

There is no complete remedy within the foreseeable future, Dr. Metcalfe Brown concludes, but the greater part of the problem can be attacked by building better homes, by planning towns to avoid congestion, by improving working conditions still further, by promoting health education, and by curtailing atmospheric pollution.

Influenza

Deaths from influenza are still on the increase: in the 160 great towns of England and Wales there were 446 deaths in the week ended Feb. 7, compared with 313, 132, and 72 in the three preceding weeks. The majority of deaths were again in London and the south-eastern region, where 270 people died as against 219 in the week ended Jan. 31. There were slight increases in all the other regions with the exception of the eastern region: but there is still no evidence of any serious spread to the north, and the disease continues in its mild form. The number of first claims for sickness benefit submitted to the Ministry of National Insurance decreased in most regions, including London, in the week ended Feb. 10, though there were slight increases in some parts of the north, the midlands, Wales, and Scotland. The epidemic is discussed in an annotation on p. 383.

The epidemic has fallen heavily on a number of schools in and around London.[1] At one stage Eton had 300 of its 1160 boys ill, and at Tonbridge more than half the boys were affected, but the outbreak is now subsiding.

Appointments

CHAYTOR, R. G., M.B. Durh., D.L.O.: consultant E.N.T. surgeon, hospitals in Newcastle upon Tyne and Gateshead H.M.C. groups.

DISON, GERALD, M.C., L.R.C.P.E., D.OBST., D.P.H.: asst. administrative M.O.H., Birmingham.

KALINSKY, SIDNEY, M.B. Lpool: whole-time tuberculosis M.O., North Liverpool area.

McDOUGLE, H. A., M.B. Edin.: asst. anæsthetist (S.H.M.O.), Hull "A" and East Riding groups.

MARKS, K. L., M.B. Edin., M.CH. ORTH. Lpool, F.R.C.S.E.: whole-time asst. orthopædic surgeon, hospitals in the Chester area.

PEGUM, J. S., M.A., M.D. Camb., M.R.C.P.: physician to the skin department, London Hospital.

PERRIN, JOHN, M.B. Camb., M.R.C.P.: asst. director to clinical laboratories, London Hospital.

RICE-OXLEY, J. M., M.A., D.M. Oxfd, M.R.C.P.: consultant physician, hospitals in Chesterfield, Worksop, and Retford.

WATKINS, P. F. A., M.R.C.S.: area M.O., Swindon (British Railways, Western Region).

WELLS, C. E. C., M.B. Lond., M.R.C.P.: medical registrar, Southmead Hospital, Bristol.

WHITEHEAD, J. P. S., M.R.C.S.: asst. pathologist (S.H.M.O.), Scarborough, Bridlington, Malton, and Whitby group.

Colonial Service:

DANSEY-BROWNING, G. C., M.R.C.S., D.O.M.S.: ophthalmic specialist, Hong-Kong.

DASENT, L. E., M.B.: M.O. Grade C (late student), Trinidad.

DAS GUPTA, P. R., M.B., F.R.C.S., D.L.O.: M.O. (E.N.T.), British Guiana.

KENT, P. W., O.B.E., M.B., D.P.H., D.T.M. & H.: special grade M.O., Kenya.

McLAREN, D. W., M.B. Durh., D.T.M.: senior M.O., Nigeria.

ONWU, S. E., M.B. Edin., D.T.M. & H.: D.D.M.S., Eastern Region, Nigeria.

Dublin Corporation Tuberculosis Service:

CALLAGHAN, BRENDAN, L.R.C.P.I., D.P.H.: asst. M.O.

FLANAGAN, J. J., M.B. N.U.I.: asst. M.O.

McDONAGH, ANNA, M.B. N.U.I.: asst. M.O.

WALSH, BRIDGID, M.B. N.U.I.: asst. M.O.

Births, Marriages, and Deaths

BIRTHS

EWING.—On Feb. 11, at Hammersmith Hospital, Ducane Road, W.12, to Phyllis (née Parnall), wife of Mr. Maurice R. Ewing, F.R.C.S.—a brother for Hamish.

RIGBY.—On Feb. 5, to Joan, wife of Dr. J. P. V. Rigby, of Huntsmoor Weir, Cowley, Middl[illegible]

TURNER WARWICK.—On Jan. 2[illegible] Margaret (née Harvey Moore), [illegible] Turner Warwick, F.R.C.S.—a daughter.

WOLLNER.—On Feb. 8, at The Churchill Hospital, Oxford, to Sylvia Wollner, M.B. (née Colquhoun), wife of Leopold Wollner, M.B.—a son (Mark Edward).

1949	M	49	3	,, ,,	9th ,,	,,
1950	F	31	4	Surgical shock	4 hr postop	1st side
1951	M	52	4	,, ,,	12 ,, ,,	2nd side

Operations

Patients operated on by the Smithwick method underwent resection of the splanchnic nerves through a posterior infradiaphragmatic approach, plus removal of the sympathetic chain from the level of the 8th dorsal ganglion to the 2nd lumbar ganglion In some patients the upper limit of section varied by one or two ganglia, particularly in the earliest operations, when removal did not extend above the 10th dorsal ganglion When the more extensive procedure began to be used in 1947, the approach was by a formal thoracotomy with excision of the seventh rib The sympathetic chain was divided between dorsal ganglia 3 and 4, and through a diaphragmatic incision the dissection was carried downwards to the level of the 2nd lumbar vertebra This approach does not allow, with certainty, excision of the 2nd lumbar ganglion (Boyd and Monro 1949) Subsequently this technique was modified for reasons given below, so that through a single skin incision the posterior ends of the 5th and 9th ribs were excised, making the limits of the dissection easier, and the sympathetic chain was removed from ganglion D2 to L2 inclusive

Operative Mortality and Complications

Contrary to expectation, the more extensive operation was not associated with a higher mortality There were 9 (7 3%) operative deaths among 122 patients (table v)

Empyema developed in a patient who had the extrapleural Smithwick type of operation *Postoperative effusion* developed in all the patients who underwent the Grimson type of operation, but aspiration was necessary in less than half *Acute hypotension*, particularly during or shortly after the operation on the second side, caused much anxiety but could be controlled by blood-transfusion, with methedrine, and by elevation of the foot of the bed Though *oliguria* was often met in the early postoperative days, in no case did it occasion much worry With increasing experience of the surgical problems, and the use of noradrenaline in particular, control of the blood-pressure during and after operation has been more readily achieved

TABLE VI—EFFECT OF OPERATION ON ACTIVITY

Group	No of cases	Postoperative activity		
		Increased	Unchanged	Decreased
2	29	19	6	4
3	49	27	10	12
4	14	7	3	4
Total	92	53	19	20

Postural hypotension after operation was seen in various degrees in most patients but passed off within three to six months A supporting belt was, however, necessary in 6 patients, 5 others complained of tachycardia and breathlessness on exertion or even on standing upright In 3 patients this has persisted without alteration since operation over two years ago

Vasospasm of the hands has followed operation in 24 patients 10 have developed mild symptoms, such as increased coldness and numbness of the hands in cold weather, 11 have stated that in addition to coldness their hands go blue more often than before operation, and in 3 the changes are identical with a mild Raynaud's phenomenon All these changes took place in patients early in the series In later cases the operation was therefore extended up to and including ganglion D2, and these unpleasant sequelæ now seem to have been eliminated

2 women developed *asthmatic symptoms* after the operation In one the symptoms were mild, and in the other severe for a year, later abating In the severe case the extensive type of operation, up to and including D2, had been performed

Intercostal neuralgia has followed the operation in several patients In 2, a woman and a man, it was severe and did not appear to be relieved by injection of local anæsthetic or even division of the posterior nerve roo of the affected segment 4 other patients have complained of less severe but persistent pain in their scars It has been noticed that most of the patients who have undergone transthoracic sympathectomy for hypertension complain much more of pain in the operation site during the immediate postoperative period than do other patients on the same unit who have undergone major thoracotomy for other conditions Smithwick (1951) has noticed this increased tendency to wound pain in hypertensives, and has tried to give a physical explanation for it

TABLE VII—POSTOPERATIVE BLOOD PRESSURE

Systolic blood pressure changes	Smithwick operation	Grimson operation	Diastolic blood pressure changes	Smithwick operation	Grimson operation
Increased by more than 60 mm Hg	3		Increased by more 40 mm Hg	3	1
Increased by 30–60 mm Hg	9	3	Increased by 20–40 mm Hg	7	1
Unchanged—i e, from 30 mm Hg above to 30 mm Hg below preoperative level	11	15	Unchanged — *i e*, from 20 mm Hg *above to 20 mm* Hg below pre *operative level*	17	16
Decreased by 30–60 mm Hg	10	11	Decreased by 20–40 mm Hg	6	12
Decreased by more than 60 mm Hg	3	6	Decreased by more than 40 mm Hg	3	5

Results of Operation

Symptoms

The immediate improvement in *headaches* has been striking, and in all the patients was virtually complete immediately after the operation This relief persisted in practically all the cases irrespective of the postoperative blood pressure levels 84 patients complained of severe headaches as a presenting symptom, and 53 of these have had no further headaches after the operation The remaining 31 obtained relief from headaches for various periods, but later the headache returned to some extent In 24 it was mild and of much less intensity and frequency than previously, but in the other 7 it has again become severe Of those with serious visual impairment—i e, all grade-IV patients and some grade III (65 cases)—all but 2 showed improvement, with disappearance of papillœdema and resolution of hæmorrhages and exudates These 2 patients had already suffered permanent damage to their optic nerves one has been totally blind for seven years with optic atrophy, though otherwise fit and well, the other has lost the upper half of his visual fields and has shown no improvement over the last six years

Exercise and Work Capacity

An attempt has been made to assess results by taking as a base line the normal activity of the patient before the onset of the symptoms which ultimately led to admission to hospital "Activity increased" means that the patient had returned successfully to the employment in ctor may be called upon to do. I remember, when a dresser, at the house-surgeon suggested a dental surgeon should be sked to treat a patient then in the ward. This suggestion icited the characteristic reply 'What is the use of a house-rgeon who can't draw teeth?' Within twenty-four hours at house-surgeon and the dresser learnt quite a lot about ental surgery.

"But it was after he retired, that I really came to know ir Holburt, for he often came to stay during the time I ractised in the West Country. He was unusually well formed about the simple things that interest ordinary folk, nd on one occasion when he went to a tennis party with s he was a tremendous success. Yes, he mellowed when old."

Another former student recalls the army-like discipline hat was traditional on the Waring firm.

"Clean white jackets, well-polished shoes, sharp scissors, nd torches that worked, were expected on parade, when e waited for him near the fountain. He expected from us omplete knowledge of our cases and diagnoses as detailed nd tabulated as items listed in a Civil Service inventory. Hernia, inguinal, right,' you were supposed to say and, by ay of encouragement, he would continue in unison with you, indirect, epiploenterocele, reducible, recurrent, non-strangu-ated.' But incorrect answers would call forth his displeasure nd often his favourite epithet—'you pink flamingo!'—eaning that you were a perfectly useless creature possessing owever slight ornamental value.

"He always stood with a perfectly straight back and he xpected others to do the same: the hands were often in the ockets of the white coat. His hair was snowy white and lentiful, and his blue eyes fierce and commanding as he ooked at you in a somewhat supercilious and sometimes even defiant way. His voice, always subdued at the bedside, had nasal quality, while his address tended to be bullying in one. But his manner was assertive rather than arrogant and he inspired affection rather than fear, for conscientious work won his respect though not his praise. He never smiled, but he was not unfriendly or unapproachable.

"He was at his fieriest in the theatre, but the roar and thunder of his voice as he moved from the first table to the second disturbed no-one but the novice and the occasional visitor. His bark was always far worse than his bite, and the chief assistant and the theatre sister, for whom he had profound respect, always had the situation well in hand.

"Then there was that great formality of his famous dinner parties for his dressers. I have fleeting memories of the long mahogany table in the beautiful room, a lavish display of crystal glasses, lace and silver, the thrill of the wines, the dinner jackets of one's carefully groomed colleagues, and the affable conversation of our chief. Only then and at the firm's Christmas concert did one see the light of kindliness momentarily break through the stern blue eyes of this essentially shy man."

While Sir Holburt was treasurer, A. D. W. relates, the capital of the Imperial Cancer Research Fund was trebled and its annual expenditure quadrupled.

"The two major developments of the Fund during his time have been largely due to his instigation—the obtaining of a royal charter and the erection of the Fund's *own* premises and move from Queen Square to Mill Hill. Both were carried through under his close supervision, and the Fund will always be in his debt for the ability and devoted care which he gave not only to these major questions but to all its financial and legal affairs during his long period of office."

In 1900 Sir Holburt Waring married Annie Cassandra, daughter of Mr. C. J. Hill, who died in 1948. Their only child, Mr. A. H. Waring, who succeeds to the baronetcy, is a research engineer with Imperial Chemical Industries.

BERTRAM MITFORD HERON ROGERS

B.A., D.M. Oxfd

Dr. Bertram Rogers, who died at Oxford on Feb. 9, at the age of 92, had passed most of his professional life in Bristol. His father, J. E. Thorold Rogers, M.P., was professor of political economy at Oxford and at King's College, London. From Westminster School, Rogers entered Exeter College, Oxford, where he gained a blue for association football. He continued his medical studies at University College Hospital, London, and qualified in 1889, taking his D.M. three years later.

On first going to Bristol, he engaged in general practice, but he was soon appointed physician to the Bristol Children's Hospital, and he always took a special interest in children's diseases. He played an active part in the public and professional life of the city. For some years he was secretary of the Bristol Medico-Chirurgical Society's journal, and in 1910 he was elected president of the society. As the subject of his presidential address he chose Medical Aspects of Boswell's *Life of Johnson*. Another paper based on his wide reading was his article in the *Times* in 1937, describing his discovery of two unpublished letters of Lewis Carroll. He was chairman of the Bristol branch of the St. John Ambulance Association, and treasurer of the local Royal Empire Society branch. During the 1914–18 war he commanded a field ambulance. He was highly esteemed by his colleagues; but few if any of them are living still, to mourn his loss.

WALTER HENRY GRACE

B.Sc. Sydney, M.D. Lond., F.R.C.P.

Dr. Grace, lecturer in forensic medicine and toxicology in the University of Liverpool, and forensic pathologist for the Home Office in the north-west region, died on Feb. 10 at his home near Chester.

Born in Australia in 1892, he took his B.SC. with first-class honours in the University of Sydney. Soon afterwards he came to England, where he continued his medical education at Guy's Hospital, graduating M.B. in 1918, and proceeding to the M.D. in 1922. He held several house-appointments at Guy's before he became senior assistant bacteriologist to the hospital.

A few years later he was appointed pathologist to Chester Royal Infirmary, and he quickly won for himself an authoritative position as a medicolegal consultant in North Wales, Liverpool, and the West Midlands. He became a member of Middle Temple in 1938, and in the same year was appointed to his lectureship at Liverpool University. In 1939 he was elected F.R.C.P. For some years he was an examiner for the universities of London, Glasgow, and Leeds.

In 1947 he was appointed to his Home Office post, and he figured prominently in many murder investigations and trials in the North of England, including the "Hanging Boy" case, the Cameo, Neston, and Red Wharf Bay murders, and those associated with the names of Dr. Ruxton and Dr. Clements. About a year ago increasing physical limitations led him to retire from active medicolegal practice.

"The essence of Grace's nature," writes J. M. L., "was gentleness, kindness, charm, and an unfailing courtesy. His quiet, genial manner appealed alike to colleagues, students, and laymen. His wide sympathies, combined with a delightful sense of humour, endeared him to all with whom he came into contact. He was popular with his students, who will long remember his flashes of wit and apposite commentaries on current events and problems. He was an interested observer of the academic comedy, and he enjoyed the arguments at meetings of the faculty of medicine and found a certain relish in the business of committees."

In his picture of Dr. Grace, K. S. recalls "a leonine head of near-white hair and a slow deliberation of manner which gave him a presence which seemed far older than he was—but provided a deceptive veneer to a mind that grasped the essentials of a forensic problem, foresaw the trend of cross-examination, and could adhere with a calm unshakable determination to a view he had decided was proper. These are the fundamental assets of a good witness—for both prosecution and defence; and Grace acquired the respect of each, making many friends on the Bench and at the Bar.

"He was no iconoclast, and often sought out his colleagues to sound his opinion before committing himself in court. The Euston Hotel was his choice of milieu for such meetings—with Spilsbury, Eric Gardner, Keith Simpson, or maybe an old Guy's colleague whose special experience he wished to probe, and the hotel staff plainly allowed him much latitude in these friendly consultations, which might last far into the night. Grace presented his facts lucidly and with a nice sense of humour, showed himself a good raconteur—but never failed to listen, to test theory by his academic knowledge and experience, and to express his gratitude with a courtesy that, if it sounded a little portentous, was none the less genuine. He worked hard and relaxed little, found it impossible to detach himself sufficiently to write, and may not therefore figure greatly in the history of medical jurisprudence. He

Bechgaard (1950) for the surgical and non-surgical series are represented graphically in figs. 1, 2, and 3 with the comparable survival-time curves from our series. In group 3 separate analyses for the two sexes are made, but in group 4, because of the smallness of the numbers (20) separate analyses have not been undertaken and the composite graph is compared with the mean values for males and females from Hammarström and Bechgaard's group-4 cases. We have further corrected our results, taking into account the normal life-expectancy of patients of the same sex and age as in our series. (The results were also graphed on logarithmic paper, but the graph lines so made did not show sufficient change from those published to warrant their inclusion.)

In preparing the graphs (figs. 1, 2, and 3) of the survival-times in the various groups the number of patients surviving at the end of each yearly period has been expressed as a percentage of the number at risk. Only patients who survived the operations have been included in these graphs. Those who died as a result of the operation or in the immediate postoperative period have been detailed separately (table v). The numbers surviving from each year and the survival-times of those who have died during the following period are listed in table x.

Pregnancy

4 patients have had *pregnancies* since operation: 1 has had two children, and 2 have had one each, without any deterioration in their condition. The 4th patient had a cæsarean section at 7½ months, after developing severe toxæmia, but the subsequent course was satisfactory (Newell and Smithwick 1947).

Discussion

Ignorance of the ætiological factors as well as of the natural life-history of hypertension naturally contributes to the confusion that attends any attempt to assess the results of therapy. In recent years, however, our knowledge has been increased by Keith et al. (1939), Bechgaard (1946), Burgess (1948), Palmer et al. (1948), Frant and Groen (1950), White et al. (1950), and Hammarström and Bechgaard (1950). Bechgaard (1946), by his follow-up of 1000 cases, has provided us with a most useful base-line against which can be measured the results of any form of treatment.

TABLE X—YEARLY ANALYSIS OF SURVIVING PATIENTS AND SURVIVING TIMES OF THOSE WHO DIED IN FOLLOW-UP PERIOD

SURVIVAL-TIME

Palmer et al. (1948) from a follow-up of [illegible] patients for an average period of eight years, concluded that a survival-rate of [illegible]% at the end of five years in group-4 patients, or of two-thirds of the patients in group 3 for a similar period, would constitute the clearest proof of effectiveness of any form of therapy. The true effectiveness in groups 1 and 2 cannot be so easily assessed, since these groups include a great number in whom the pattern that the disease is going to follow cannot be foretold—e.g., most will be slowly progressing benign hypertensives, whose expectation of life is only little affected by the condition.

The figures available from a considerable series of cases untreated or medically treated agree, within narrow limits, on the mortality in cases of groups 3 and 4. Hammarström and Bechgaard (1950), in a series grouped similarly to ours, found that in non-surgically treated group-4 cases the mortality-rate at the end of five years was 88% (female) and 85% (male), and at the end of ten years 99%. For group-3 cases the five-year mortality-rate was 62% (male) and 30% (female), and at ten years 87% (male) and 55% (female).

We do not believe that isolated examples or small series of cases of severe hypertension as recorded by Page (1939), Flaxman (1944), Blood and Perera (1948), Burgess (1948), Perera (1948), and many other workers, which seem to have undergone subsequent remission, invalidate these figures. The mortality-rate for the present series at five years is 40%, and at seven years 43% for group-4 patients, although the series comprised many more male than female patients. In group 3 the corresponding figures were 25% (male) and 16% (female) at five years. There has been no death in group 2 (29 cases) in the follow-up period.

This significant increase of survival-time, which was one of the most striking findings of this follow-up study, accords with the experiences of Hammarström and Bechgaard (1950), Peet and Isberg (1946), Smithwick (1951), Palmer (1947), Poppen and Lemmon (1947), and Evans and Bartels (1949).

SYMPTOMS

Symptomatic improvement to a degree which can be produced by no other form of therapy has been reported by numerous workers, and objective evidence of regression, such as improvement in eye grounds, has long been noted (Wells and Welbourn 1950, Smithwick 1951, d'Abreu 1948, Hammarström 1947, Grimson 1949). Reasons for this symptomatic improvement are difficult to find in our present state of knowledge but may be contained in the two demonstrable effects of sympathec-
tomy—nam[illegible] alteration of vasomotor tone in the
non-sympat[illegible] areas, and a postural fall in
blood-pressu[illegible] may persist for years after the
operations [illegible] of headache may be due to
increased (c[illegible] vasomotor tone in the non
[illegible] thecto[illegible] which prot[illegible] the capillaries
[illegible] the [illegible]-pressure [illegible] would explain

morning and evening, he attended church in Exeter, and, though he never discussed his religion there is no doubt that it meant everything to him, and guided the whole conduct of his life."

JAMES ARTHUR KERR

V.R.D., M.D., B.Sc. Glasg., D.P.H.

We have to record the death of Dr. J. A. Kerr, medical officer of health for the county borough and port of Grimsby, on Feb. 10, at the age of 51.

Born in Glasgow, he was educated at the High School and University of his native city. His undergraduate career was interrupted by service as a surgeon probationer in the Navy during the first world war, but he qualified in 1923. He took his D.P.H. two years later, and while working for this studied law and became a member of the Middle Temple. His M.D. was obtained with commendation in 1928. He held resident posts in the Western Infirmary, Glasgow, and became successively senior assistant medical officer at Manchester City Fever Hospital, deputy medical officer of health for Chester, and senior assistant medical officer of health for Birmingham.

His services to Grimsby, where he was appointed M.O.H. in 1931, were of a high order, for they were based alike on ability, energy, courage, and sympathy. Characteristically, he was fully engaged in public duties until the evening before his brief terminal illness. For twenty years he had been handicapped by severe physical disability, but he had remained an unusually dynamic figure, always a leader in planning improvements in the town's medical facilities and always ready to help his colleagues either in their day-to-day difficulties or in any cause which he felt justified his support. He was fearless in expressing his views, and he put them forward with a vigour which made him a valuable and much respected member of any committee.

In the second world war he again served in the Navy and he was awarded the King Haakon VII Liberation Medal for outstanding services in connection with the liberation of Norway. He remained a surgeon commander, R.N.V.R.

Among his local appointments, Dr. Kerr was the school medical officer and was consultant in infectious diseases at Springfield Isolation Hospital. He was a member of the Grimsby Hospitals Management Committee, the local medical and local obstetric committees, and the local executive council. His broad and accurate knowledge and his good will enabled him to maintain excellent relations between his department and his colleagues in general practice. His handling of the poliomyelitis epidemics in 1938 and 1947 and the smallpox epidemic in 1947 earned high praise from those who worked with him. Largely owing to his foresight and enthusiasm, an almoner service was established in the health department in 1949, and the mental health services were founded and steadily improved. It was with Dr. Kerr's coöperation that Dr. J. W. Brown established his well-known clinics for heart-disease and rheumatism. He was also a very active member of the Lincolnshire Joint Cancer Committee, whose pioneer scheme made specialist treatment available to many who otherwise would not have had it. His professional interests extended outside Grimsby and he was president of the East Midland branch of the Society of Medical Officers of Health for 1949–50, and an examiner to the Royal Sanitary Institute. He was also a member of the general and medical committees of the Association of Sea and Air Port Health Authorities of the British Isles. His published work includes articles on puerperal sepsis and its cardiac and pulmonary complications, on fish inspection, and on the treatment of poliomyelitis.

To the end of his life, he found time for numerous activities outside medicine. In Grimsby he was president of the Royal Naval Association, president of the Grimsby and Cleethorpes Rotary Club, and chairman of the international service committee of Rotary. He was chairman of the civilian committee of the Sea Cadet Corps, and president of the Hard of Hearing Association, which he helped to found.

In 1933, he married Doreen, daughter of the late Dr. A. M. Nevin of Birmingham, and she survives him with two sons and a daughter.

Notes and News

PRESCRIPTION COSTS

Presenting the civil appropriation accounts,[1] the Comptroller and Auditor-General remarks that in 1950 18% of all prescriptions under the National Health Service in England and Wales, and 26% of those in Scotland, were for proprietary preparations. In England and Wales the 18% accounted for 33·5% of the total cost of prescriptions. In 1951 the percentage of prescriptions for proprietary preparations increased to 23 in England and Wales and to 30 in Scotland; and in April, 1952, a sample analysis of prescriptions in England and Wales showed a further rise to 25·6%.

SCHOLARSHIPS ABROAD

The British Council has published a booklet giving details of about 100 scholarships offered by 17 foreign governments and universities to British students for study abroad during 1953–54. Further information may be had from the controller of the education division of the council, 65, Davies Street, London, W.1.

University of Cambridge

On Feb. 6 the following degrees were conferred:

M.D.—I. S. Hodgson-Jones.

M.B., B.Chir.—* I. M. Brown.

* By proxy.

Royal College of Surgeons of England

At a meeting of the council on Feb. 12, with Sir Cecil Wakeley, the president, in the chair, Mr. Geoffrey Keynes was presented with the Cecil Joll prize.

Prof. Ian Aird (Postgraduate Medical School) and Mr. F. W. Holdsworth (Sheffield) were re-elected and Mr. E. S. Lee (Westminster Hospital) was appointed to the court of examiners for the next three years. Mr. A. H. Lendon (Adelaide) and Prof. H. R. Dew (Sydney), the present Commonwealth travelling professor, were elected members for one year.

A Hunterian lectureship was awarded to Prof. Wilder Penfield, O.M. (Montreal), and a Moynihan lectureship to Dr. H. L. Jaffe (New York). The Hallett prize was awarded to A. T. Matheson (Cape Town), and the Handcock prize to A. H. Tooley (King's College Hospital).

Diplomas of membership and postgraduate diplomas were granted to those named in our report (Feb. 7, p. 303) of the comitia of the Royal College of Physicians.

Hunterian Festival Dinner.—At this dinner on Feb. 13 Sir Cecil Wakeley, the president, said that the Queen had graciously consented to lay the memorial stone of the new buildings on May 5. He was also happy to announce that the Duke of Edinburgh had promised to come to the college to receive the honorary fellowship in the autumn. Good progress was being made with the new college: the framework and floors of the Great Hall and the dining-room of the Nuffield College of Surgical Sciences were complete; and the Wellcome museums, the new council room, and the library extension were beginning to take shape. There were hopes of making a start on the main block of the Nuffield College later this year. Sir Cecil said that this was probably the last Hunterian dinner to be held in the present library, for the Great Hall should be ready in good time for the festival of February, 1955. A great deal of research work was in hand at the college, and the president referred particularly to the plans of the department of pharmacology which were being generously supported by certain pharmaceutical firms. Sir Cecil was replying to the toast of The College, proposed by the Minister of Health, Mr. Iain Macleod. Sir James Paterson Ross extended a friendly welcome to the large company of guests, for whom Sir Denys Lowson replied. Sir Reginald Watson-Jones, proposing the toast of The Hunterian Orator, said how magnificently Mr. Lionel Norbury had paid homage to the memory of John Hunter in his oration earlier in the day. Mr. Norbury, in a brief reply, spoke of the pleasure and satisfaction to be derived from a study of the history of medicine; his own researches into the Hunterian era had proved an absorbing source of interest.

---

[1] Civil Appropriation Accounts (classes I–VIII), 1951–52. H.M. Stationery Office. Pp. 487. 14s.

Bechgaard (1950) for their surgical and non-surgical series are represented graphically in figs 1, 2, and 3, with the comparable survival-time curves from our series In group 3 separate analyses for the two sexes are made, but in group 4, because of the smallness of the numbers (20), separate analyses have not been undertaken, and the composite graph is compared with the mean values for males and females from Hammarstrom and Bechgaard's group-4 cases We have further corrected our results, taking into account the normal life expectancy of patients of the same sex and age as in our series (The results were also graphed on logarithm paper, but the graph lines so made did not show sufficient change from those published to warrant their inclusion)

In preparing the graphs (figs 1, 2, and 3) of the survival-times in the various groups the number of patient's surviving at the end of each yearly period has been expressed as a percentage of the number at risk Only patients who survived the operations have been included in these graphs Those who died as a result of the operation or in the immediate postoperative period have been detailed separately (table v) The numbers surviving from each year and the survival-times of those who have died during the following period are listed in table x

Pregnancy

4 patients have had *pregnancies* since operation 1 has had two children, and 2 have had one each, without any deterioration in their condition The 4th patient had a cæsarean section at $7^1/_2$ months, after developing severe toxæmia, but the subsequent course was satisfactory (Newell and Smithwick 1947)

Discussion

Ignorance of the ætiological factors as well as of the natural life-history of hypertension naturally contributes to the confusion that attends any attempt to assess the results of therapy In recent years, however, our knowledge has been increased by Keith et al (1939), Bechgaard (1946), Burgess (1948), Palmer et al (1948), Frant and Groen (1950), White et al (1950), and Hammarstrom and Bechgaard (1950) Bechgaard (1946), by his follow-up of 1000 cases, has provided us with a most useful base line against which can be measured the results of any form of treatment

TABLE X—YEARLY ANALYSIS OF SURVIVING PATIENTS AND SURVIVING TIMES OF THOSE WHO DIED IN FOLLOW-UP PERIOD

Year	Group 4		Group 3 (M)		Group 3 (F)		Group 2

SURVIVAL-TIME

Palmer et al (1948) from a follow up of 430 patient for an average period of eight years, concluded that a survival-rate of 20% at the end of five years in group-4 patients, or of two thirds of the patients in group 3 for a similar period, would constitute the clearest proof of effectiveness of any form of therapy Therapeutic effectiveness in groups 1 and 2 cannot be so easily assessed, since these groups include a great number in whom the pattern that the disease is *going to follow* cannot be foretold—e g , most will be slowly progressing benign hypertensives, whose expectation of life is but little affected by the condition

The figures available from a considerable series of cases untreated or medically treated agree, within narrow limits, on the mortality in cases of groups 3 and 4 Hammarstrom and Bechgaard (1950), in a series grouped similarly to ours, found that in non surgically treated group 4 cases the mortality-rate at the end of five years was 88% (female) and 85% (male), and at the end of ten years 99% For group 3 cases the five year mortality rate was 62% (male) and 30% (female), and at ten years 87% (male) and 55% (female)

We do not believe that isolated examples or small series of cases of severe hypertension as recorded by Page (1939), Flaxman (1944), Blood and Perera (1948), Burgess (1948), Perera (1948), and many other workers, which seem to have undergone subsequent remission, invalidate these figures The mortality-rate for the present series at five years is 40%, and at seven years 43%, for group-4 patients, although the series comprised many more male than female patients In group 3 the corresponding figures were 25% (male) and 16% (female) at five years There has been no death in group 2 (29 cases) in the follow-up period

This significant increase of survival time, which was one of the most striking findings of this follow up study, accords with the experiences of Hammarstrom and Bechgaard (1950), Peet and Isberg (1946), Smithwick (1951), Palmer (1947), Poppen and Lemmon (1947), and Evans and Bartels (1949)

SYMPTOMS

Symptomatic improvement to a degree which can be produced by no other form of therapy has been reported by numerous workers, and objective evidence of regression, such as improvement in eye grounds, has long been noted (Wells and Welbourn 1950, Smithwick 1951 d'Abreu 1948, Hammarstrom 1947, Grimson 1949) Reasons for this symptomatic improvement are difficult to find in our present state of knowledge but may be contained in the two demonstrable effects of sympathectomy—namely, an alteration of vasomotor tone in the non-sympathectomised areas, and a postural fall in blood-pressure, which may persist for years after the operations The relief of headache may be due to increased (compensatory) vasomotor tone in the non sympathectomised head, which protects the capillaries against the raised blood-pressure This would explain the relief from headaches which occurs when the subsequent blood-pressure levels are not much reduced by operation It has been shown (Wilkins et al 1948, Bourne 1948, Tuckwell 1948, Philps 1948) that after operation the higher peaks of blood pressure are no longer reached, and because of this the heart and small blood-vessels are no longer exposed to the stress of the widely fluctuating blood pressures of essential hypertension

CAPACITY FOR EXERCISE AND WORK

Increased capacity for exercise and work can be regarded as a measure of the symptomatic improvement

SYMPATHECTOMY IN THE TREATMENT OF HYPERTENSION

REVIEW OF 122 CASES

READER IN MEDICINE, UNIVERSITY OF BIRMINGHAM

THIS paper reviews the results of thoracolumbar sympathectomy in 122 patients with hypertension treated at the Queen Elizabeth Hospital, Birmingham, between 1943 and 1951. All except 2, who were untraced after a year, have been seen and examined regularly. Up to 1947 a limited sympathectomy was performed, using techniques similar to those described by Peet et al. (1940) and Smithwick (1940); but from then onwards the more extensive resection associated with Grimson (1941) was done. The two series are not strictly comparable; but, when some additional information is thereby gained, separate analyses have been made.

TABLE I—GROUP, SEX, AND TYPE OF OPERATION IN 113 PATIENTS SURVIVING OPERATION

Operation	Group 4		Group 3		Group 2	
	Males	Females	Males	Females	Males	Females
Smithwick ..	9	1	6	20	4	10
Grimson ..	5	5	13	25	4	11
Total ..	14	6	19	45	8	21

In classifying the patients the system described by Hammarström and Bechgaard (1950) has been adopted as being more convenient than the more complicated one of Smithwick (1951) or the method of Keith et al. (1939), which is based mainly on an accurate but personal assessment of retinal changes.

Investigation and Classification of Cases

Routine investigations included intravenous pyelography, estimation of the blood-urea, analysis and concentration tests of urine, electrocardiography, radiography of the chest, and ophthalmoscopy. In some cases early in the series inulin and diodone clearances were estimated. Much interest centred at one stage on the demonstration of the hypotensive effects of amylobarbitone, tetraethylammonium bromide, sympathetic blockade by local anæsthetics, and vasodilation by various pyrogens. These tests were gradually abandoned when it was found that they added little to the information gained by recording the blood-pressure hourly for twenty-four hours and had no prognostic value.

TABLE II—AGE-DISTRIBUTION IN 113 PATIENTS SURVIVING OPERATION

Operation	Age-group (yr.)				
	10–19	20–29	30–39	40–49	50–59
Smithwick ..	1	6	13	21	9
Grimson ..	—	3	18	21	21
Total ..	1	9	31	42	30

According to the results of these investigations the patients were divided into four groups (Hammarström and Bechgaard 1950) as follows:

Group 1.—Hypertension, with no secondary vascular complications, and either no subjective symptoms or only slight symptoms.

Group 2.—Hypertension. Marked subjective symptoms. No signs of myocardial damage or vascular change. Left axis-deviation on electrocardiography and/or a relative enlargement of the left ventricle, and heart volume radiographically within normal limits. Retinal changes grade I or II (Keith et al. 1939).

Group 3.—Hypertension, with subjective symptoms and/or signs of secondary vascular complications—i.e., retinal grade-III changes (Keith et al. 1939), including retinal hæmorrhages with or without thrombosis of the retinal vessels, or retinæ grade I or II with one or more of the following: negative T wave in the electrocardiogram; heart volume above predicted normal (transverse diameter greater than half the thoracic diameter); residual damage to central nervous system after cerebral accident; or albuminuria.

Group 4.—Hypertension, with retinal exudates and papillœdema grade IV (Keith et al. 1939).

TABLE III—DISTRIBUTION OF SECONDARY VASCULAR MANIFESTATIONS IN 64 GROUP-3 CASES

Secondary vascular complications	Grimson operation		Smithwick operation	
	Living (32)	Died since operation (6)	Living (21)	Died since operation (5)
Renal (albuminuria, &c.)	23	6	8	2
Lesions of central nervous system	23	4	16	4
Cardiac (E.C.G. changes, &c.)	19	6	6	4
Retinitis grade III ..	23	4	15	3

No. of systems affected ..	1	2	3	4
Living	23	23	6	1
Died since operation ..	4	5	1	1

The composition of each group is further analysed by sex and age in tables I and II.

Essentially, group 3 contains all the patients with evidence of secondary vascular damage of the retinal, cerebral, cardiac, or renal vessels. Many had involvement of more than one system, and it will be noted (table III) that coronary and renal damage was associated with the highest mortality since operation.

TABLE IV—PREOPERATIVE BLOOD-PRESSURES IN 113 PATIENTS SURVIVING OPERATION

Diastolic B.P. (mm. Hg)	Group 4	Group 3	Group 2	Systolic B.P. (mm. Hg)	Group 4	Group 3	Group 2
Over 180	2	4	..	Over 240	2	5	2
160–180	6	12	2	210–240	10	29	14
140–160	8	24	10	180–210	8	25	9
120–140	4	22	11	150–180	..	5	4
110–120	..	2	6				
Total	20	64	29	..	20	64	29

ESTIMATIONS OF BLOOD-PRESSURE

A very large series of preoperative blood-pressure readings was collected for each patient, and the selection of a figure which could be called "the blood-pressure" for each case was a most difficult task. We took the view that the occasional very high or very low figure in the records of most patients had little value for comparison with "casual" follow-up figures, since our patients were not readmitted for serial postoperative blood-pressure readings. We have therefore chosen as the preoperative level in each case the resting recumbent pressure taken on the second or third day in hospital. Table IV gives the preoperative diastolic and systolic levels in the 113 cases available for observation.

SELECTION OF CASES

It must be emphasised that only in a small proportion of hypertensives is sympathectomy indicated We exclude from consideration the mild symptomless hypertension which is met in group 1 of the present classification A few patients in group 2 should be considered for surgery when the symptoms have become incapacitating despite the usual remedial measures When they are first seen at this stage it is impossible to predict how the disease will progress Experience shows that many remit, some follow a slow benign course, and only a very few develop at a more rapid tempo into "severe benign" or malignant types.

The onset of secondary vascular changes characteristic of group 3 brings with it further considerations At this stage the prognosis is no longer in doubt, and the urgency of treatment is measured by the rate of deterioration, which can be assessed from the history, the age, and a short period of observation It is important that the slowly developing benign hypertensives should be recognised when met in this group They are usually aged 50–60 and are unsuitable for surgery Palmer (1947) has called attention to this type and has termed it "burnt out benign hypertension" We believe that active hypertensive disease can be arrested at this stage by sympathectomy, and that some of the apparent failures to do so are due to mistaken diagnosis and failures on technical and anatomical grounds In view of the low mortality the surgical risk is acceptable for the very considerable benefits to be gained, particularly if more conservative measures are unsuccessful Undoubtedly this group will contain some hypertensives with primary renal disease, but we have no evidence that, if the renal function is reasonably good, the operative risk is affected For group-4 patients sympathectomy is indicated if two or three months' complete rest and adequate treatment with hypotensive drugs cause no evident interruption of hypertension or its symptoms Failing improvement in these circumstances the decision should not be deferred too long, because the surgical risk is thereby increased Our best results have been obtained in malignant hypertensives under the age of 40 We regard congestive cardiac failure, poor renal function, and advanced arteriosclerosis as contra indicating surgery, and prefer our patients to be under the age of 50, although many in the present series were over that age

Summary

The classification suggested by Hammarstrom and Bechgaard (1950) has been used in reviewing the results of thoracolumbar sympathectomy in 122 patients treated in 1943–51

The results, together with those reported by other workers, support the view that operation prolongs life and produces substantial symptomatic and objective improvement irrespective of its effect on the blood-pressure

It was considered that the operation was indicated in a small proportion of group-2 cases for the relief of incapacitating headache, for most cases in group 4, and for those cases in group 3 with actively progressing hypertensive disease uncontrolled by other measures

The surgical mortality, though high in group 4, was 3% in group 3 in the series reviewed, and nil in group 2

The view is expressed that mistaken diagnoses, technical difficulties, and anatomical factors may be responsible for some of the anomalous findings

We wish to express our thanks to the physicians of the Queen Elizabeth Hospital, Birmingham, under whose care many of these patients were admitted and whose help and coöperation made the review possible The operations in addition to our own were performed by Dr William H Sweet, of the Massachusetts General Hospital, Boston, Mass (officer in charge of a neurosurgical unit "on loan" from the United States 1941–45), Prof Brodie Hughes, Prof F A R Stammers, Mr A L d'Abreu, and Mr A Gourevitch We are indebted to Dr John Waterhouse, of the department of medical statistics, University of Birmingham, for his guidance and help in the analyses

THE clinical picture of temporal arteritis was first described by Hutchinson more than sixty years ago (Hutchinson 1890) in the octogenarian father of a London Hospital beadle The man was quite bald and developed red painful streaks on his head which prevented him from wearing his hat The red streaks were inflamed temporal arteries the branches of which could be traced and almost met in the midline At first feeble pulsation could be detected in the arteries, but later these became pulseless, lost their redness, and were left as impervious

READER IN MEDICINE, UNIVERSITY OF BIRMINGHAM

THIS paper reviews the results of thoracolumbar ympathectomy in 122 patients with hypertension treated t the Queen Elizabeth Hospital, Birmingham, between 943 and 1951. All except 2, who were untraced after year, have been seen and examined regularly. Up to 947 a limited sympathectomy was performed, using echniques similar to those described by Peet et al. 1940) and Smithwick (1940); but from then onwards he more extensive resection associated with Grimson 1941) was done. The two series are not strictly comarable; but, when some additional information is hereby gained, separate analyses have been made.

TABLE I—GROUP, SEX, AND TYPE OF OPERATION IN 113 PATIENTS SURVIVING OPERATION

Operation	Group 4		Group 3		Group 2	
	Males	Females	Males	Females	Males	Females
Smithwick ..	9	1	6	20	4	10
Grimson ..	5	5	13	25	4	11
Total ..	14	6	19	45	8	21

In classifying the patients the system described by Hammarström and Bechgaard (1950) has been adopted as being more convenient than the more complicated one of Smithwick (1951) or the method of Keith et al. (1939), which is based mainly on an accurate but personal assessment of retinal changes.

Investigation and Classification of Cases

Routine investigations included intravenous pyelography, estimation of the blood-urea, analysis and concentration tests of urine, electrocardiography, radiography of the chest, and ophthalmoscopy. In some cases early in the series inulin and diodone clearances were estimated. Much interest centred at one stage on the demonstration of the hypotensive effects of amylobarbitone, tetraethylammonium bromide, sympathetic blockade by local anæsthetics, and vasodilation by various pyrogens. These tests were gradually abandoned when it was found that they added little to the information gained by recording the blood-pressure hourly for twenty-four hours and had no prognostic value.

TABLE II—AGE-DISTRIBUTION IN 113 PATIENTS SURVIVING OPERATION

Operation	Age-group (yr.)				
	10–19	20–29	30–39	40–49	50–59
Smithwick ..	1	6	13	21	9
Grimson ..	—	3	18	21	21
Total ..	1	9	31	42	30

According to the results of these investigations the patients were divided into four groups (Hammarström and Bechgaard 1950) as follows:

Group 1.—Hypertension, with no secondary vascular complications, and either no subjective symptoms or only slight symptoms.

Group 2.—Hypertension. Marked subjective symptoms. No signs of myocardial damage or vascular change. Left axis-deviation on electrocardiography and/or a relative enlargement of the left ventricle, and heart volume radiographically within normal limits. Retinal changes grade I or II (Keith et al. 1939).

Group 3.—Hypertension, with subjective symptoms and/or signs of secondary vascular complications—i.e., retinal grade-III changes (Keith et al. 1939), including retinal hæmorrhages with or without thrombosis of the retinal vessels, or retinæ grade I or II with one or more of the following: negative T wave in the electrocardiogram; heart volume above predicted normal (transverse diameter greater than half the thoracic diameter); residual damage to central nervous system after cerebral accident; or albuminuria.

Group 4.—Hypertension, with retinal exudates and papillœdema grade IV (Keith et al. 1939).

TABLE III—DISTRIBUTION OF SECONDARY VASCULAR MANIFESTATIONS IN 64 GROUP-3 CASES

Secondary vascular complications	Grimson operation		Smithwick operation	
	Living (32)	Died since operation (6)	Living (21)	Died since operation (5)
Renal (albuminuria, &c.)	25	6	8	2
Lesions of central nervous system	23	4	10	4
Cardiac (E.C.G. changes, &c.)	19	6	6	4
Retinitis grade III ..	23	4	15	3

No. of systems affected ..	1	2	3	4
Living	23	23	6	1
Died since operation ..	4	5	1	1

The composition of each group is further analysed by sex and age in tables I and II.

Essentially, group 3 contains all the patients with evidence of secondary vascular damage of the retinal, cerebral, cardiac, or renal vessels. Many had involvement of more than one system, and it will be noted (table III) that coronary and renal damage was associated with the highest mortality since operation.

TABLE IV—PREOPERATIVE BLOOD-PRESSURES IN 113 PATIENTS SURVIVING OPERATION

Diastolic B.P. (mm. Hg)	Group 4	Group 3	Group 2	Systolic B.P. (mm. Hg)	Group 4	Group 3	Group 2
Over 180	2	4	..	Over 240	2	5	2
160–180	6	12	2	210–240	10	29	14

120–140	4	22	11	150–180	..	5	4
110–120	..	2	6				
Total	20	64	29	..	20	64	29

ESTIMATIONS OF BLOOD-PRESSURE

A very large series of preoperative blood-pressure readings was collected for each patient, and the selection of a figure which could be called "the blood-pressure" for each case was a most difficult task. We took the view that the occasional very high or very low figure in the records of most patients had little value for comparison with "casual" follow-up figures, since our patients were not readmitted for serial postoperative blood-pressure readings. We have therefore chosen as the preoperative level in each case the resting recumbent pressure taken on the second or third day in hospital. Table IV gives the preoperative diastolic and systolic levels in the 113 cases available for observation.

and ACTH given intramuscularly or by slow intravenous drip, produced changes far beyond their usual tonic and euphoric effect Pyrexia, head pains, and arterial tenderness rapidly subsided, appetite improved, and in some cases there was a dramatic change from apathy and misery to alertness, cheerfulness, and interest One patient (case 4) had been ill for six months and, when treatment was started, had pyrexia up to 101°F, severe head pains, and grossly inflamed temporal and occipital arteries She was given eleven daily intravenous drips of ACTH , the pyrexia, headache, arterial tenderness, and inflammation rapidly subsided, and at the end of the course of treatment she felt completely well Another (case 9) had pyrexia, severe headache, tenderness of the scalp, and the grossest cranial arteritis She was so ill that a fatal issue was highly probable, but within seventy-two hours of the institution of cortisone therapy her pyrexia, head pains, and tenderness of the scalp had disappeared and she was alert and subjectively well

The answer to the second question, as to whether a brief period of treatment with cortisone is curative, seems equally definite Though symptoms and objective evidence of active disease always disappeared very rapidly, the erythrocyte-sedimentation rate remained high (cases 3, 4, 7, 9, 10, and 12) In this connection it must be pointed out that for weeks or months a raised ESR is often the only definite evidence of the disease , but, so long as it is present, vision is constantly threatened, a cerebral or coronary vascular catastrophe may occur at any time, or cranial arteritis or severe constitutional symptoms may develop One patient (case 11) died of a coronary occlusion four weeks after ACTH therapy, and follow-up of others (cases 7, 8, and 9) showed that the disease was still active months after the cessation of treatment

One patient (case 10) appeared to be cured, apart from a raised ESR , after fifteen days' intramuscular ACTH therapy, but with diminishing doses her pyrexia, head pain, and arterial tenderness returned and there was an obvious deterioration in her general condition Dosage was therefore increased, and within two or three days she was once more subjectively and objectively normal ACTH therapy was continued for a further twenty-three days, and to date (twelve months after the cessation of treatment) she has remained in normal health, apart from some residual visual loss Altogether she had ACTH for forty-two days, and for ten days before it was stopped her ESR was only just outside the normal range

Another patient (case 9) had previously had a peptic ulcer, and though cortisone therapy rapidly controlled the symptoms and signs of temporal arteritis (apart from the ESR) it had to be stopped because of a severe recrudescence of ulcer symptoms Within a few days head pains, pyrexia, and general malaise recurred and the abdominal symptoms subsided Further cortisone therapy once more produced a remission of the temporal arteritis, but ulcer dyspepsia returned For four months temporal arteritis and peptic ulceration alternately called for treatment, and three and six months after the patient's discharge from hospital the ESR was still grossly raised

It appears, therefore, that maintenance therapy is required, and in only 2 of our cases (nos 10 and 12) was it possible to continue treatment until the disease reached its natural end The cause of temporal arteritis is probably not an infection, and ACTH and cortisone presumably produce their effect by blocking some sensitisation mechanism Before they can be said to have cured the disease, their administration has to be continued until there is no longer any sensitisation to block

Visual Loss

The results obtained in the 10 of our 12 patients who had ocular involvement were as follows

(1) 4 patients (cases 3, 5, 6, and 7) had been totally blind for periods ranging from six days to four weeks when treatment was begun, and in none did any vision return

(2) 1 patient (case 1) had had partial loss of vision from five to eight months before ACTH therapy, and no improvement resulted

(3) 5 patients (cases 2, 8, 9, 10, and 11) had had partial loss of vision for periods of ten days or less All showed some improvement in their visual acuity, and visual fields after cortisone or ACTH therapy, but the degree of change was relatively small, and in none was normal sight restored

It may well be that the improvement that took place in the third group was that which so often occurs naturally after any thrombotic incident and was quite unrelated to cortisone therapy The results obtained, however, are of some value in management, both from the prognostic and therapeutic aspects, and might have been better if more prolonged therapy had been possible Total blindness and long-standing partial loss of vision are unlikely to improve, and cortisone will probably not help them When loss of vision is partial and recent, some amelioration is likely with cortisone therapy (and possibly without it), but normal sight is unlikely to return The chief value of cortisone or ACTH in such cases is without doubt to control the arteritis as long as it lasts and so to safeguard any vision that remains

CASE-RECORDS

Case 1 —A man, aged 68, was admitted in November, 1950, with asthenia, loss of weight, and pain in the right loin, where a mass was palpable The results of radiography after a barium enema and of intravenous pyelography were normal, but the urine contained pus and blood A renal neoplasm was suspected, and the right kidney was therefore explored and removed Histological examination showed chronic pyelonephritis The patient's general health did not improve, and he had severe headaches and scalp tenderness In March, 1951, the vision of his right eye suddenly deteriorated, and three months later his left eye was similarly though less severely affected He was readmitted in November, 1951, when the occipital and temporal arteries were thickened and tender but still pulsating There was no pyrexia, and the ESR was 16 mm at one hour (Wintrobe) There was no anæmia or leucocytosis The fundi were normal apart from arteriosclerotic changes, and the visual acuity was 6/6 (part) right and 6/5 (part) left The left visual field was full, but only central vision remained in the right eye The patient was given 20 mg of ACTH by slow intravenous drip each day for ten days Though his general condition improved and his head pains disappeared his visual acuity and visual fields did not alter Three months later he still had active temporal arteritis

Case 2 —A man, aged 83, was admitted to hospital with typical temporal arteritis a few days after experiencing sudden diminution in vision in both eyes On admission the visual acuity in the right eye was reduced to the appreciation of hand movements, and the visual field to a small temporal wedge The left eye had a visual acuity of 6/12 and a full visual field The patient was given a slow intravenous drip of 20 mg of ACTH daily for five days His left eye did not improve, but the whole of the right temporal field was restored, and visual acuity in this eye was 6/60 when he left hospital

Case 3 —A woman, aged 79, had six months' history of malaise, loss of weight, anorexia, and pains in the neck, arms, and legs, and five weeks' history of severe temporal and occipital pain and tenderness of the scalp Twenty two days before treatment was begun she suddenly lost all vision in the right eye, and four days later the left eye also became totally blind The discs were pale, their edges were indistinct and the retinal arteries were narrow and irregular There was a low pyrexia, the temporal arteries were tender and apulsatile, and the ESR was raised, being 29 mm at one hour (Wintrobe) She was given large doses of cortisone intramuscularly for nine days and, though there was striking subjective improvement, and the pyrexia and head pains rapidly subsided, no vision returned and the ESR remained high

Case 4 —A woman, aged 77, was admitted with six months' history of pains in the head, shoulders, neck, and ears, which

which he or she was engaged before the onset of severe symptoms. "Activity as before operation" includes many patients whose activity, though improved, has not permitted them to resume their usual work. In the lowest category are placed the patients who lead a semi-invalid existence postoperatively, and in these cases activity has been decreased since the operation. 92 cases were followed up sufficiently to allow an assessment to be made (table VI).

Blood-pressure

About a third of the patients who underwent the Smithwick type of operation, and half of those who underwent the Grimson operation, have shown an appreciable reduction of blood-pressure (table VII). Readings were taken in the recumbent position after a resting period of fifteen to twenty minutes.

The latest blood-pressure readings in the 36 Smithwick-type cases followed up for between five and nine years, and the 35 Grimson-type cases followed up for three to five years have been analysed in tables VIII and IX; those of under three years' observation are not included. 13 patients (18%) have a diastolic pressure of below 100 mm. Hg, and 40 (56%) less than 120 mm. Hg. Preoperatively no patient had a diastolic blood-pressure below 110 mm. Hg, and only 8 (11%) had one below 120 mm. Hg. 10 patients (14%) show a systolic pressure of less than 150 mm. Hg, and 32 (45%) one less than 180 mm. Hg, whereas the preoperative figures are none and 9 (13%) respectively. These figures refer to 71 patients of the 113 under observation; of the remaining 42, 21 have died since operation and 14 of the Grimson type have been followed for less than three years. The remaining 7 patients are known to be alive and well, but live away from Birmingham, and records of their blood-pressures are not available.

Electrocardiogram

Of the patients who had survived five years following operation 33 had abnormal electrocardiograms preoperatively, well-marked left axis-deviation, and, more commonly, T-wave changes of "left ventricular strain," and hypertrophy. Of these, 14 became completely normal, 6 had improved to show only left axis-deviation, and the remaining 13 showed no essential change.

Survival-time

The effect of sympathectomy on survival-time noted by various workers (Smithwick 1951, Hammarström and Bechgaard 1950)—namely, that expectancy of life in hypertensives is considerably increased by the operation—is further confirmed, and survival-time is directly related to the grouping: group 4 (those with papillœdema) has the gravest prognosis; group 3 (secondary vascular complications) has a less grave prognosis; and group 2 has the best chance of survival. Group 1 is not considered, because none in this category was operated on. The life-expectancy tables of Hammarström and

temporal arteries were thickened, tender, and apulsatile A blood count was normal, but her E S R was 32 mm at one hour She was given intramuscular A C T H for fifty-two days Within six days of the start of therapy her headache and arterial tenderness disappeared and her general condition showed a striking improvement On discharge her E S R was 24 mm and she has since remained completely well

SUMMARY

The clinical features and pathology of temporal arteritis are briefly recounted, and the characteristics and diagnostic value of the headache and visual loss are emphasised

Twelve cases treated with cortisone or A C T H are described In ten the vision was affected.

A C T H and cortisone controlled the disease in all the cases, but relapse occurred when treatment was stopped. Maintenance therapy appears to be required until the disease reaches its natural termination

The total blindness of four patients and the long-standing partial loss of vision in one other patient were not altered by cortisone therapy, but in five patients with recent partial loss of vision there was some improvement in visual acuity and visual fields, which may have been due to cortisone therapy

CONTROLLED HYPOTENSION IN NEUROSURGERY

WITH SPECIAL REFERENCE TO HYPOTENSION INDUCED BY PNEUMATIC SUCTION APPLIED TO THE LEGS

ANTHONY JAMES

RESEARCH ASSISTANT, DEPARTMENT OF MEDICINE, OTAGO UNIVERSITY MEDICAL SCHOOL, DUNEDIN

A METHOD has been described (Saunders 1952) by which adequate falls of blood-pressure were produced by hexamethonium bromide (H M B) during anæsthesia with the patient maintained at or near the horizontal posture Suction was applied to the legs by encasing them in airtight metal cylinders connected to a suction pump of large capacity

We know of no report making a direct comparison between neurosurgical cases operated on with and without controlled hypotension using H M B as the hypotensive agent In the present paper we compare 150 cases in which no attempt was made to lower the pressure (normotensive group) with 150 cases in which such an attempt was made (hypotensive group)

Hypotension was produced by H M B and suction to the legs in 50 of the patients in the hypotensive group, and by H M B and posture in the remaining 100 Technical modifications have now been made to the suction apparatus (see below), though the principle remains the same

TABLE I—AGE, SEX, AND NUMBER OF PATIENTS UNDERGOING EACH TYPE OF OPERATION IN THE TWO GROUPS

—	Normotensive group	Hypotensive group
Operation		
Craniotomy	102	75
Laminectomy	10	68
Miscellaneous	38	7
Total	150	150
Sex		
Male	80	89
Female	70	61
Age (years)		
Youngest	8	8
Oldest	81	72
Mean	39	42

The 300 cases comprise all those operated on in this unit between Oct 4, 1950, and July 28, 1952, except 43 operations (leucotomy 14, abscess aspirations 2, and 27 on children under eight years of age) omitted because there were no comparable cases in the hypotensive group.

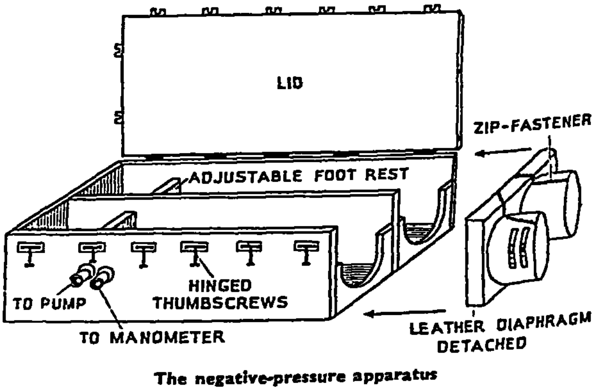
It will be noted from table I that there is a preponderance of laminectomies in the hypotensive group This is because initial experience of the technique was gained with that operation

Since it has been suggested that cerebral, cardiac, and renal ischæmia are liable to result from hypotension, electrocardiograms have been recorded and the cerebral venous oxygen content has been estimated at the low blood-pressures during operation Observations have also been made on the renal function

NEGATIVE-PRESSURE APPARATUS

By the time that H M B alone had been used in 80–90 cases its limitations, particularly in craniotomies, had become apparent In only half of them was a successful degree of hypotension and hæmostasis obtained A tilt of the operating-table of at least 30° was required, which was the maximum acceptable to the surgeon For all posterior-fossa, and for most frontal, craniotomies a much smaller tilt was essential to allow surgical access Hence H M B could not be used for these operations

For these reasons the negative-pressure device described by Saunders (1952) was devised This was similar in principle to the apparatus with which Restall and Smirk (1951, 1952) produced falls of blood-pressure in conscious persons The metal cylinders originally used (Saunders 1952) have now been replaced by a rectangular wooden box with a hinged lid (see figure) The patient's legs lie on either side of a wooden partition whose function is to prevent buckling of the lid with the negative pressure The lid is held closed by hinged



The negative-pressure apparatus

among the cases of lesser severity—i.e., group 2 and one in group 3. In more severe cases it reflects the diminution in heart size and improvement in signs of congestive failure and encephalopathy. 5 patients with congestive cardiac failure have been operated on; 2 of these have already survived three and five years and have returned to their work, an experience noted by Chavez and Mendez (1949) in 8 of 11 such patients.

ELECTROCARDIOGRAM

The finding of left ventricular strain on electrocardiography has also influenced us in undertaking operation. Canabal et al. (1945) have shown that the chances of such electrocardiographic changes reverting to normal without operation are about one in ten. After thoracolumbar sympathectomy the electrocardiogram became normal in a third, and there was some degree of improvement in a further third, of the cases. Peet and Isberg (1948) noted that 52% of their cases with abnormal electrocardiograms became normal. Similar trends were noted in our patients. Leishman (1951) suggests that this may be due to the diminution in size of the heart, and again our observations tended to confirm this suggestion. Indeed, the electrocardiographic findings are one of the truly objective measurements of benefit to be obtained by sympathectomy.

RENAL EFFECTS

Early in the series 16 renal biopsy specimens were taken. 2 patients with healed pyelonephritis and 1 with evidence of chronic glomerulonephritis underline the great difficulty that may be met in excluding patients who have a primary renal cause for their hypertension. Such patients will naturally alter the prognosis. Unless biopsies are routinely taken, even with the defects of such methods, any series would be likely to contain similar patients (Platt and Stanbury 1950), since the available clinical methods of diagnosis are insufficiently accurate. Persike et al. (1949) have operated on patients in the terminal stage of glomerulonephritis and claimed satisfactory results. Of their 10 patients 1 died as the result of the operation, 2 could not be followed, and 2 died at six and ten months, but the other 5 returned to work for periods up to forty-nine months at the time of publication. Since these patients had serum-creatinine levels varying from 2·22 to 8·75 mg. per 100 ml., blood-pressures between 184/134 and 290/185 mm. Hg, and visual disturbance, and were totally incapacitated, the reports suggest that severe kidney damage need not be an absolute bar to operation if other circumstances favour it.

BLOOD-PRESSURE

Much of the adverse criticism of the surgical treatment of hypertension is based on its failure to reduce the blood-pressure in the majority of cases (Evelyn et al. 1949, McMichael 1952, Platt and Stanbury 1950). Too much preoccupation with this single measurement of the disease tends to divert attention from other equally objective tests of improvement, such as reduction of cardiac size, and improvement shown on electrocardiography, exercise tolerance, fundi, and survival-times.

Patients were operated on because their symptoms had become incapacitating despite other forms of treatment, or because they had begun to exhibit such evidence of secondary vascular disease that steady deterioration was the only prognosis. Blood-pressure levels alone did not justify operation. Though it is true that the higher the blood-pressure the worse is the outlook (Frant and Groen 1950), it is often difficult to decide the true level of the preoperative blood-pressure. On reviewing the results it was soon evident that lability of blood-pressure was no guarantee of success in reducing it by operation, whereas a relatively fixed raised blood-pressure did not necessarily rule out a highly successful result. For example, the first patient to undergo operation, a man aged 28, had a fixed hypertension with a diastolic blood-pressure of 130–140 mm. Hg, and visual acuity limited by papillœdema to perception of light only, yet now, almost ten years later, he is working overtime as a toolsetter with only a slightly raised blood-pressure.

These observations agreed with the view, widely held, that blood-pressure readings, except in the highest levels, are of little importance in assessing the severity of essential hypertension. What are more important are (1) the rate of progress of the secondary vascular changes in the cerebral, renal, and cardiac vessels, (2) evidence of cardiac decompensation or coronary thrombosis, and (3) evidence of impending renal failure, such as constant albuminuria, hæmaturia, and inability to concentrate urine.

Comment on the effects of surgery on the blood-pressure would be incomplete without consideration of the anatomy of the sympathetic system which makes complete excision a difficult technical procedure (Mitchell 1947). This is well recognised in connection with the minimal ablations required to denervate the limbs. In the case of thoracolumbar sympathectomy not only is the resection much more extensive but also there is little opportunity of testing its completeness in the splanchnic and renal areas, and such indirect tests as may be used suggest that resection is often far from complete (Boyd and Monro 1949).

We have tried to correlate the postoperative progress of our patients with their blood-pressure levels, and have been unable to find a relationship. Some, in whom the blood-pressure has been lowered to normal and has remained so, have had their activity diminished, whereas others, whose blood-pressure was unaffected, were symptomatically and objectively improved. Several of the patients who died soon after operation showed a progressively rising blood-pressure during the period of their survival.

SURGICAL MORTALITY

Mortality from sympathectomy is related to the proportion of group-4 patients in any series. In the present review 7 of the 9 deaths within the immediate postoperative period were in group 4. 27 patients in group 4 were operated on, and the 7 deaths give an operative mortality of about 26%. We regard this high figure as a measure of our attempt to save some of the most advanced cases with cardiac and/or renal insufficiency rather than as an indication of the risk the operation entails in a fairly fit patient. In 66 cases in group 3 there were 2 deaths (about 3%), and of the 29 patients in group 2 none died. In a brief reference to his results Learmonth (1950) stated that his mortality-rate for all cases accepted for surgical treatment was "just under 3%." Recently Blainey (1952) published the results of a series of cases treated in this hospital with hexamethonium compounds. In a personal communication he has given us the mortality-rates while the patients were under medical treatment. In his series there were 7 group-4 patients, but 2 of these were aged more than 60 and are not comparable to ours. The remaining 5 patients (aged 34–36 years) all died within nine months while undergoing treatment with hexamethonium. In group 3 there were 8 patients, but 1 was over 60 years of age, the remainder being between 45 and 52. Of these 7 patients 2 died within a year of starting treatment. Blainey's figures in group 4 regarding mortality are only for a very small group of cases, but the fact that there is also a mortality from medical treatment should be borne in mind, a point sometimes omitted when the efficacy of various therapeutic substances is being assessed (*British Medical Journal* 1952).

Craniotomies			
Number	102	39	36
Mean total H.M.B. (mg.)	—	104	65
Satisfactory hypotension and hæmostasis	—	54%	75%
Patients requiring transfusion	64%	69%	39%
Pints per patient of whole series	0.95	1.05	0.66
Mean duration of anæsthesia (hours)	4³/₄	4¹/₄	4¹/₄
Mortality	18.6%	15.4%	11.1%
Laminectomies			
Number	10	55	13
Mean total H.M.B. (mg.)	—	75	46
Satisfactory hypotension and hæmostasis	—	60%	92%
Patients requiring transfusion	50%	9%	8%
Pints per patient of whole series	0.5	0.15	0.15
Mean duration of anæsthesia (hours)	3¹/₄	3	3
Mortality	20%*	0	0

* The 20% mortality shown for laminectomies in the normotensive group is misleading. This represents 2 patients only, of whom one had a widespread retroperitoneal sarcoma from which she died some weeks later, and the other died from massive pulmonary embolism.

in the normotensive group. The duration of anæsthesia was again reduced, and the mortality fell to just over half the original level. With suction to the legs the number of patients in whom satisfactory hypotension and hæmostasis were obtained was increased from 54 to 75% and the requisite dose of H.M.B. decreased by a third.

With laminectomies hypotension produced an even greater fall in the number of patients requiring transfusion, and operating time was decreased as with the craniotomies. The suction technique when used for laminectomies proved especially valuable in increasing the number of satisfactorily hypotensive patients. As can be seen, an adequate fall of blood-pressure is now obtained in practically every patient.

Thus, in both craniotomies and laminectomies, the suction technique has proved more satisfactory in every way than H.M.B. combined with posture, and in addition the patient can be maintained at, or near, the horizontal posture, thus giving increased safety for the patient and increased convenience for the surgeon.

Mortality

The deaths mentioned are those which took place before the patient left hospital, all but 3 being within a month of operation. 10 patients in the hypotensive group of 150 died, compared with 24 in the normotensive group. Necropsies were made in all of these. This decrease in death-rate is attributed largely to improved surgical treatment. The 20% mortality shown in table III for the laminectomies in the normotensive group is misleading. This represents 2 cases only: one patient had an untreatable sarcoma invading the spinal canal, from which she ultimately died, and the other died from massive pulmonary embolism.

There was only one death in the hypotensive group attributable to the hypotensive technique.

This was in a hypertensive woman, aged 51, with a ruptured aneurysm on the middle cerebral artery, which was wrapped with muscle at operation. She received 25 mg. of H.M.B. in one intravenous dose and a moderate degree of suction (40 mm. Hg). This produced a satisfactory hypotensive result. Postoperatively her blood pressure rose within five hours to its preoperative level of 180/110 mm. Hg, whereupon she was given three further doses of H.M.B. at hourly intervals in an unsuccessful attempt to keep her blood pressure below 150/100. She became drowsy eight hours *after* operation, slowly lapsed into coma by next day, and died six days later. At necropsy unsuspected bilateral congenital cystic kidneys and a cystic liver were found, and the condition of the brain was satisfactory. If the condition of her liver and kidneys had been known before operation, the hypotensive technique would not have been used, and only the smallest possible amount of iodine contrast medium would have been used for arteriography.

Apart from this case, the causes of the deaths in the normotensive and the hypotensive groups were similar. The majority were due to raised intracranial pressure, in some cases associated with intracerebral hæmorrhage. In addition, 4 patients in the normotensive group died from massive pulmonary embolism. There were no such cases in the hypotensive group. Thus there seems to be nothing to suggest that the application of negative pressure involving the use of non-constricting leather cuffs round the thighs is associated with an increased tendency to thrombus formation in the legs.

Complications

Unusual complications arose in only 2 of the hypotensive group during their stay in hospital.

(1) A young man, aged 27, who had a cervical laminectomy and a partial removal of a meningeal sarcoma, became blind in one eye suddenly on the third postoperative day. This was thought to be a minor embolic phenomenon, although the ophthalmoscopic appearances were not pathognomonic of occlusion of the retinal artery. The hypotensive technique was thought not to be responsible.

(2) A man, aged 65, had a cervical laminectomy and section of the posterior roots of C8, T1, and T2 for intractable left ulnar nerve pains. On recovering consciousness he had a transient weakness of the right palate, vocal cord, and sternomastoid muscle, which was thought to be due possibly to a spasm or minor thrombosis in part of the territory of the right inferior cerebellar artery. He recovered completely. The hypotensive technique could have been responsible in this case.

No postoperative intracerebral hæmatomata have occurred in the hypotensive group. In 2 cases of pituitary tumour the conscious state deteriorated postoperatively and a re-exploration was done. No hæmatoma was found, however, in either case, and the defect of consciousness was found to be due to an endocrine imbalance and rapidly responded to substitution therapy (Caughey et al. 1952).

Follow-up

Of the 94 surviving patients who received H.M.B. alone, 74 were re-examined at intervals of one to thirteen months after discharge, with a mean follow-up period of five months. No untoward symptoms have appeared. The cases treated with H.M.B. and suction have not yet been followed for a significant period but have as yet shown no untoward effects.

Estimations of Cerebral Venous Oxygen

Samples of blood were taken under anaerobic conditions from either the cranial venous sinuses or the cerebral veins of patients undergoing craniotomies. In no case was there any undue reduction of the venous oxygen content at the hypotensive levels used.

Electrocardiography

Electrocardiograms were recorded on patients before, during, and after hypotension, and no changes were found suggesting myocardial ischæmia. Two of these patients had known coronary-artery disease.

One, a woman aged 70, tolerated a systolic blood pressure of 60 mm. Hg satisfactorily at operation. The other, a woman aged 52, who was not for operation, had hypertension (220 mm. Hg systolic) and angina of effort accompanied by pronounced electrocardiographic changes with exercise. The anginal pain and electrocardiographic changes were regularly produced by 30 paces on the flat. The systolic pressure of this patient was gradually lowered, while she was conscious, to 60 mm. Hg by H.M.B. and posture, and there was no anginal pain or electrocardiographic change suggesting myocardial anoxia at that pressure.

ends. The patient lived for several years after this lness.

Though Schmidt (1930) described a further case, it was through workers at the Mayo clinic (Horton et al. 932, 1934, Horton and Magath 1937) that the clinical nd histological features became widely known and ppreciated. It was they who suggested the name "temporal arteritis" and emphasised many of the major linical features—the mature age of the patients, the rotracted nature of the malady, the pyrexia, anæmia, nd leucocytosis, the loss of weight, and the inflammation ound the temporal arteries. Nothing has since been dded to their description of the histological changes, he features of which are round-cell infiltration round he vasa vasorum in the adventitia, the replacement f the media by granulation tissue, with the partial or omplete disappearance of the elastic laminæ, infiltration f the media with plasma cells, lymphocytes, and giant ells and sometimes areas of hæmorrhage, together with cellular thickening of the intima, often associated with thrombosis.

Horton and his colleagues held that temporal arteritis was relatively benign and its duration limited to a few months. Such prognostic optimism has, however, not been justified by the experience of subsequent workers, for Cardell and Hanley (1951) point out that in 27 of 37 published cases the patients died during the active phase of the disorder. The cause of death was in most cases coronary or cerebral thrombosis; and, though it is possible that the coincidence of such incidents was fortuitous, since temporal arteritis only occurs during the degenerative period of life, it is more probable that they were part of a generalised arteritis. Ample evidence has been provided to show that temporal arteritis is part of a generalised vascular disease, fatal cases having shown similar histological lesions in the aorta and carotid, innominate, subclavian, pulmonary, cœliac, mesenteric, renal, iliac, radial, and coronary arteries (Sproul 1942, Chasnoff and Vorzimer 1944, Cooke et al. 1946, Cardell and Hanley 1951).

Bacteriological examination of numerous biopsy specimens has not revealed a cause, and the ætiology remains unknown.

CLINICAL FEATURES

More than 150 cases have now been published and the condition has been extensively reviewed (Harrison 1948, Crosby and Wadsworth 1948, Migone and Mortara 1949, Cooke 1951, Cardell and Hanley 1951). The main features of temporal arteritis are essentially those set out by Horton and his colleagues and can be readily comprehended from the case-records given below. The condition is not uncommon, and, when once a typical patient has been seen and the modes of presentation are appreciated, most practitioners are likely to recognise examples. From our experience of more than 30 cases, two features appear to warrant further comment—namely, headache and disturbances of vision.

Headache is a constant feature of the disease. The organic causes of headache in later life are few; and, though cerebral tumour, hypertension, glaucoma, and Paget's disease have to be considered, the headache of temporal arteritis has unique features which immediately suggest the diagnosis to anyone familiar with the condition. Usually throbbing, but sometimes aching or lancinating, the headache is very severe, preventing sleep and often persisting relentlessly for weeks. It is commonly confined to the areas of the temporal and occipital arteries, and often the scalp is so tender that even mastication and laying the head on a pillow are painful. Such headaches should always lead to a careful examination of the temporal and occipital arteries and their branches.

Visual complications.—Ocular involvement has been variously estimated as 33% (Kilbourne and Wolff 1946), 40% (Anderson 1947), 33% (Harrison 1948), 35% (Migone and Mortara 1949), and 38% (Cardell and Hanley 1951). Of the 31 cases which we have observed ocular involvement occurred in 16, and 8 of the patients became totally and permanently blind. The symptoms prefacing such catastrophes have been varied. Loss of vision may be sudden "like a blind being drawn across," or it may be preceded by one or more episodes of transitory amblyopia or diplopia. Papillœdema and retinal hæmorrhages are often but not always evident, and later the features of optic atrophy develop in which the disc is slightly filled in and has a curious creamy appearance. Where total blindness does not ensue, any form of loss of the visual field may take place. Histological studies have shown that the ophthalmic and retinal arteries may be involved by the same type of arteritis as occurs in the temporal and other arteries, narrowing of the lumen or thrombosis being responsible for the visual loss. We would suggest that any elderly patient who has transitory amblyopia or sudden loss of sight should be carefully examined for tender temporal or occipital arteries, and his symptoms should be reviewed as possibly due to temporal arteritis.

TREATMENT
